Key. — The large majority of people, however, need help in associating the position of the tones in the keys with the notes. Such a device we have in the famous *do re mi*, or syllable names, dating back to the eleventh century, and attributed to Guido of Arezzo. This association is made possible when the key is established, the tones of the scale taking on certain characteristics. When, therefore, a certain syllable is always sung to a certain tone in the key, when the sign for a syllable is written, it suggests the relative tone in the key it represents. The principle underlying this use of the syllable names had a revival in France under the leadership of Pierre Galin, a music publisher of the early nineteenth century, who indicated the relationship of tones by numbers. In England John Curwen utilized the sound names attributed to Guido. In the system thus developed, called the "Tonic sol-fa," the fixed pitch representation of the staff was ignored, and the first letter of the syllables, *do, re, mi*, etc., were printed instead of numbers, for example, *d, r, m*. The spacing of these letters indicated the duration of the tones. These letters, like the numbers, drew attention to the relationship of the sounds to be sung, and not to any given pitch, and are evidently a vocalist's notation.

The American methods follow the English usage, and some places even adopt the Tonic sol-fa notation as an introduction to sight-reading; but the ordinary practice is to use the syllable names with the staff notation. This brings about a complexity that does not exist where the syllables are used with the Tonic sol-fa notation, for reading by note requires a student of harmony to determine the proper relative name from the fixed notation that the staff represents, especially in modern music, which tends to be more and more chromatic

and makes it difficult to determine what the exact key relationship of a tone is. Another difficulty grows out of the constant use of the Tonic sol-fa names, especially where the syllable names have been too slavishly used. The tendency is to associate the tone to be sung not simply with the sight or sound of the name, but with its actual physical production, so that the pupil is able to sing the tune if he can sing sound names, but is unable to think the tune apart from the names. In order to avoid this difficulty many schools use numbers instead of sound names. The objection to this is that the number names do not lend themselves to good tone production, and when too closely followed this method is open to the same objection as the use of the sound names. The chromatic tendency of modern music above referred to is making these methods less and less effective.

Interval. — Besides thinking of tones in their relation to key, we may think of them as determined by their distance from each other as intervals of seconds, thirds, and fourths having certain common characteristics. When this has been thoroughly grasped, one is enabled to sing these distances by thinking the nature of the interval. Mr. Samuel Cole of the New England Conservatory in his sight singing course has given specific names for each interval. By always using the name with the interval whenever it occurs, associations are formed between the interval character of tones and the name, so that, when the interval name is thought, the tones occur to the mind.

Rhythm. — The teaching of duration and time grouping of tones does not present such a variety in the methods employed. The demand on the pupil, unlike that of thinking pitch relations, is identical for both singer and player. A few fundamental differences in tone lengths are used over and over, whatever the key, although confusion is caused to young students by changes in the note used to represent the beat. This difficulty is being reduced, there being a tendency among publishers to use uniformly a quarter note to represent the beat in simple time. Besides beating the time, other physical movements for strengthening the feeling for pulse in music are being employed in a more varied way.

In Europe much interest has been awakened by the work of M. Jacques Dalcroze, who has developed a remarkable feeling for rhythmic character through dancing and gesture. Movements of the march and folk dance are advocated for developing rhythmic feeling as a support for musical work.

Present Procedure. — The pressure of more and more studies in the school is tending to lessen the time given to singing. A fair average allotted to this subject is one hour a week, sometimes given in two half hours, sometimes in fifteen-minute periods. This hour is often supplemented by another period of music

work and general exercises. The music study period generally commences with some breathing exercises, followed by scale and vocal practice. Then technical matter pertaining to notation is followed by reading new music or exercises, and the lesson ends with a review of familiar songs.

In the first grade learning songs by imitation, or "rote singing," as it is called, is largely emphasized, and in some schools this is carried on in diminishing extent through the grades. This makes it possible to introduce a great deal of excellent music, which might otherwise be too difficult to read. On the other hand, those schools employing sight reading do little rote work after the first grade, paying much more attention to the singing of exercises intended to improve sight reading. This procedure reduces the artistic musical material used, but tends to increase the proficiency in reading. In either case, much depends upon the amount of individual work demanded from the pupils. The great difficulty in accomplishing any thorough teaching along ordinary lines lies in the fact that music is universally taught collectively, thus reducing the individual responsibility to a minimum, so that students can go through eight years of grade work, and at the end be unable to give the simplest description of what they have done.

New Tendencies. — The new trend in modern education is bringing about a decided change in the attitude toward the popular teaching of music. This change in aim puts the emphasis not so much on what is taught as on what the pupil can do with what he is taught. The point of interest is the pupil rather than the subject. Under this new influence the teacher aims to make the tone quality, the dynamics, the pronunciation, and the musical form, both as to pitch and rhythm, grow out of one central thought, — the expression of the feeling suggested by the words of the song. The child must sing it in a way to show that he realizes the significance of what he does.

But this is not all; the child must not only make the musical thought of another his own, but he must have experience in expressing his own poetic and musical thought, not that in so doing he can express anything of value for others, but for the sake of the musical development both in thought and taste that such practice brings about. It is parallel to theme work in the teaching of the mother tongue. This attitude toward music treats it more as a language, and seeks to make the form expressive of the feeling. In making a melody fit the words of a song the child is constantly led by the teacher to observe the relationship between the music and the text. Such effort on the part of the pupil brings about the most searching observation and thought with reference to the song he is producing, and when such song making is the collective effort of the whole class, different members offering their

versions of the wording and thought of their couplets and their melodic expression, a much more intensive exercise of æsthetic faculties and discriminative thought is brought about than ordinarily takes place by the old methods.

Thus the new methods seek to develop the poetic, imaginative, and discriminative power of the pupil in his relation to music, laying the basis for musical appreciation, which after all is the most important use to which the pupils in our public schools will put their musical education.

Training for Teachers. — Unfortunately for music in American schools, the normal schools have been unable to give the necessary training, five hours a week for half a year being the average time allowed to the subject. When this short amount of time is divided between the development of the student's own musical capacity and her training as a teacher, the inadequacy of this work will be comprehended. To meet this need the larger publishing houses are conducting summer schools for training music supervisors and grade teachers, offering courses running in some cases for three seasons. The danger in this work has been that methods advocated have been too closely allied with the particular publications of the house conducting the school. In spite of this, improvements in methods and in material have been due to the far-sighted enterprise of publishing houses rather than to the school authorities. C. H. F.

Music Schools and Conservatories. — The name Conservatory was first applied to orphan asylums where children who were particularly fitted by virtue of superior talent received a thorough musical education.

Italy. — The oldest known conservatories were founded in Naples during the sixteenth century. Four of these were combined by order of King Murat (1808) into the now existing conservatory San Pietro a Majella. The last director was Guiseppe Martucci (died 1910).

Rome. — Conservatory of St. Cecilia, founded in 1566, subsidized by the government. Perhaps the most famous Italian music school. Tuition sixty lire a year.

Palermo. — Royal Conservatory, founded in 1615. Has at present twenty teachers and about 150 students.

Venice. — Liceo Benedetto Marcello became a municipal institution in 1877. Present director E. Wolf Ferrari. Tuition very moderate, from 20 to 100 lire a year.

France. — Paris. — Conservatoire National de Musique (1795) is perhaps the best organized music school in the world, and its standards are therefore of the very highest. Among the instructors have been France's finest musicians, — Cherubine, Auber, Thomas, Dubois, Fauré, Widor, Lavignac, Lasalle, Rose Caron, Chevillard, Guilmant, Rislis, etc. The age of admission is from nine to twenty-six.

There are about 800 students and eighty-five instructors. The highest honor obtainable is the "grand Prix de Rome." Some of those receiving this distinction were Halévy, 1819, Berlioz, 1830, Gounod, 1839, Bizet, 1857, Massenet, 1863, Debussy, 1884. Branches of the Conservatoire National de Musique exist in the important towns all over France. The requirements of scholarship vary with the different localities. Noteworthy branches exist in Toulouse (1826), Lille (1826), Boulogne-sur-Mer (1884), etc. Another important school is École de Musique classique et religieuse, founded by Niedermeyer in 1853. A new school was founded in 1896 by Guilmant and D'Indy, 300 students specializing principally in organ and composition based on modern tendencies.

Germany. — Germany has developed more music schools than any other country. Some of these are under the patronage of reigning houses, others are endowed by individuals or societies, but there are numberless private schools existing and flourishing without any financial aid from outside sources.

Berlin. — Königliche Hochschule für Musik. It is divided into three sections. The oldest section is called Royal Institute of Church Music, founded in 1822. It receives only twenty students, and charges no tuition. The second section is called the Academic Master School for Composition (1833). The present masters are Bruch, Humperdinck, and Gernsheim. Tuition is free. The third section, which now is the Royal High School of Musical Art proper, was created in 1869. Joachim, the famous violinist, was the first director. Students must be sixteen years and over. The entrance examinations are very severe. A nominal tuition is charged, varying from \$7.50 to \$100 for the school year. It is interesting to know that each student costs the government on an average about \$250 a year, and yet the average tuition charged is less than \$75. Excellent private conservatories in Berlin are the Klindworth-Scharwenka School of Music and Stern's Conservatory.

Leipzig. — The Royal Conservatory, founded in 1843 by Mendelssohn, has financial guarantees from the Saxon government and the municipality. It is perhaps still the most famous conservatory in Germany. There are at present about 900 students and forty-five instructors. Some of the great musicians who taught at this school were Mendelssohn, Schumann, David Hauptmann, Richter, Gade, Moscheles, Reinecke, Ladassohn. Among the present teachers are Reger, Teichmüller, Hilf, Sitt, Straube, Klengel, etc. Famous pupils, Kirchner, Bargiel, Brassin, Ladassohn, Grieg, Sullivan, Wilhelmj, Svendsen. A peculiar position is that occupied by the Thomas School in Leipzig. Only boys with pronounced musical talent ("absolute ear" is one of the conditions) are admitted. The boys form the choir of

the Thomas Church. The boys receive a complete education without cost. The most famous director of this school was J. S. Bach.

Munich. — Royal Academy of Music (1846). The best known teachers connected with this school were and are Hans Von Bülow, Cornelius, Rheinberger, Abel, Bussmeyer, Stavenhagen, Mottl, Klose, etc. Among its students have been many Americans: George W. Chadwick, Horatio W. Parker, Fred. Bullard, Leo Lewis, Adolf Weidig.

Royal and ducal music schools of high standing exist in Dresden, Stuttgart, Würzburg, Karlsruhe, Weimar, etc. Private conservatories of first rank are to be found in Frankfurt, Hamburg, Strassburg, Wiesbaden, etc.

Austria. — Vienna. — Conservatorium der Gesellschaft der Musikfreunde admits pupils from the age of ten to twenty-four years. The German language is obligatory. The attendance is about 1000 pupils, taught by sixty-four instructors. Among the teachers of the present day are Godowsky and Sevcik.

Prague. — Conservatory of Music (1811). Bohemians receive free instruction, but bind themselves to stay six years. Besides the musical education, students receive instruction in all the important liberal branches.

Budapest. — The Royal and National Academy of Music receives students from the age of eight on. The tuition fee is nominal, and no tuition is charged for students of wind instruments, double-bass, viols, etc.

Russia. — St. Petersburg. — The most important conservatory was founded in 1862 by the Royal Russian Music Society. It is richly endowed, and has about 200 scholarships. The average attendance is 800 students, under ninety teachers. The curriculum comprises, besides the study of music, a complete liberal education. The first director was Anton Rubinstein. Famous teachers have been Glasounow, Rimski-Korskow, Essipow, Auer, etc.

Moscow. — Royal Conservatory of Music, founded by Nicolaus Rubinstein (1866), gives courses similar to the conservatory in St. Petersburg. Famous teachers have been Taneyew, Safanow, etc. There are sixty teachers, and about 600 students. The School of Music of the Philharmonic Society (1878) received in 1886 the same official recognition as the Royal Conservatories mentioned above.

There are numerous schools of music in the provinces which are considered branches of the St. Petersburg Royal Conservatory.

Belgium. — Brussels. — The Royal Conservatory of Music (1813) is one of the most important of the European institutions. Students born in Belgium pay no tuition. Those born in other countries are admitted only if acceptable to the director and the Secretary of State. Famous teachers were: Fétis, Gevaert, Tinel, De Beriot, Vieuxtemps, Leonard, Ysaye, etc.

Liège. — The Royal School of Music (1827)

is also one of the important schools in Europe. Conditions are practically the same as in Brussels.

Antwerp. — The Royal Flemish Conservatory (1867) is one of the largest institutions, and has about 1200 pupils and fifty teachers. Tuition fees are very nominal. The first director was Peter Benoit.

Netherlands. — Amsterdam. — The Conservatory of Music is under the management of the Society for Development and Protection of Music (1862). Only about eighty students over seventeen years of age are admitted. These are selected from among the pupils of the preparatory school of music, which is affiliated with the Conservatory. Well-known teachers are Zweers, Rontgen, etc.

Rotterdam. — The School of Music (1845) is under the same management as the one in Amsterdam. It admits pupils from eight years on.

Spain. — Madrid. — The Conservatorio de Maria Cristina (1830) is largely endowed by the State. There are about 1500 students and sixty teachers. Other important conservatories are maintained in Barcelona and Saragossa. All are subsidized by the government, and tuition is practically free to Spaniards.

Portugal. — Lisbon. — The Conservatorio Real (1833) is maintained by the government, which pays all expenses. There are about 300 students and thirty teachers.

Scandinavia. — Copenhagen. — The Conservatory of Music (1867) admits only fifty pupils, according to its constitution. This restriction was made by its financial founder, P. W. Moldenhauer. Lately the government has given a small subsidy, making it possible to admit about twenty-five additional students. Teachers have been, among others, G. Hartmann and N. W. Gade.

Stockholm. — The Royal Conservatory (1871) is a government institution; no tuition is charged except to a few aliens.

Christiania. — The Conservatory of Christiania (1865) is largely subsidized by a private society and the State. The tuition charged is from five to twenty-five Kronen. The present director is Lindermann.

Switzerland. — Geneva. — The Conservatory of Music (1835) has occasionally been able to engage on its teaching staff some of the best known musicians, i.e. Stavenhagen, Marteau, Jaques Dalcroze. The latter's *Rhythmic Gymnastic* bids fair to become a pronounced factor in the child's musical education. The Conservatory has about 1200 students and fifty teachers.

Basel. — Music School, director, Hans Huber. **Zurich.** — Municipal Music School, director Fr. Hegar.

Great Britain. — London. — The Royal Academy of Music (1822) was endowed by a private society. It is attended by 500 students, and has eighty instructors. Among the

famous teachers who have been connected with this school must be mentioned J. B. Cramer, M. Clementi, Bennett, Macfarren, Mackenzie.

The Guildhall School of Music (1880) is perhaps the largest music school in the world, and has approximately 4000 students and 150 instructors. It receives a subsidy from the city.

The Royal College of Music (1883) maintains perhaps the highest standards of all the English conservatories. It was founded by Arthur Sullivan as the National Training School of Music. It is richly endowed, and possesses one of the best libraries. Present director is Ch. H. H. Parry.

Other more or less important schools in London are the Royal College of Organists, director, E. H. Turpin; National College of Music, director, Dr. Tindall; London College of Music, director, I. I. Karn; Birmingham Midland Institute of Music, directors, Elgar and Bantock; Manchester Royal College of Music, director, Adolf Brodsky.

Music Departments in Universities.—Only German, Austrian, and English universities have music in the curricula. While music schools outside of universities make very few demands on their students as to liberal education, entrance into a university requires that students shall have passed final examinations in the gymnasium or preparatory college. The study of music in universities is confined to history and theory. The lectures on these subjects may be attended by students who have not passed the above-named examinations, but are admitted as special students. Only regularly matriculated students may receive the degree of Doctor of Philosophy, after submitting an approved dissertation dealing with a musical subject and showing original research. The faculties of universities sometimes bestow the degree of Doctor of Philosophy or of Doctor of Music on distinguished musicians, but *honoris causa*. Chairs of music occupied by prominent men of the "Science of Music" are to be found in Germany in the universities of Berlin, Leipzig, Bonn, Göttingen, Halle, Heidelberg, Munich, Strassburg; in Austria in Vienna, Prague, and Graz; in England at Oxford and Cambridge; and in Ireland at the University of Dublin. English universities confer the degrees of Mus. Bac. or Mus. Doc. after examination. Examinations also include the writing of *Compositions in various forms*.

United States.—It is possible at the present time to secure a thorough musical education in almost every state of the Union. This is particularly true in the larger cities or in the towns where the proximity to the larger cities offers advantages in regard to hearing concerts and attending opera. But even in more isolated places a good musical education has become possible, as some members of the faculties of educational institutions are, as a rule, ex-

cellent musicians who have received a thorough education themselves as either instrumentalists, vocalists, or theorists. It is therefore no longer necessary for music students to go to Europe for study, although it is always desirable to become acquainted with musical conditions of other countries. No music student should go to Europe until he has had a thorough education at home, and he should never leave these shores for further study abroad unless he speaks one or two foreign languages fluently. While it is true that the English language is spoken by almost every well-educated European musician, yet this is a great disadvantage to the American student, as it deprives him of the possibility of a thorough appreciation of European conditions, resulting frequently in absolutely false perspectives and erroneous conclusions.

Colleges and Universities having Departments of Music.—Harvard University.—A Music Department was established in 1862 on equal terms with the other departments. Credits of two points each in harmony and counterpoints are allowed on entrance requirements of twenty-six points. Courses offered are harmony, counterpoint, instrumentation, composition, history of music. The degree granted is the A.B., the requirements for which are eight approved courses, five in music and three in modern languages. A M. and Ph.D. candidates must be graduates of approved colleges. At least one year of residence at Harvard is demanded. The examination requirements are a thesis on musical aesthetics or history and composition for chorus and orchestra. The annual tuition is \$150. Special students are admitted, but are not eligible for degrees.

Yale University, New Haven, Conn.—The music department was founded in 1894. The courses offered are theoretical and practical. The former include harmony, counterpoint, composition, orchestration, and conducting. The practical courses are organ, piano, string instruments, singing, chamber music, and orchestral playing. The degrees and diplomas granted are certificates of proficiency in the theory of music, and the B.M. on two years' work, including two languages, one of which must be modern. Certificates are also awarded to students of practical courses. The tuition ranges from \$50 to \$200 a year.

Columbia University, New York, N.Y.—The music department was founded on an endowment of \$100,000, and the chair of music first occupied by Edward McDowell in 1896. Extra credits are given in musical appreciation or harmony—one point in a total of 14½ required for admission. The courses offered are harmony and history of music, and are open to undergraduates as electives. The degrees of B.A. and M.A. are conferred after passing satisfactory examinations in counterpoint and composition.

MUSIC IN EDUCATION

The following table gives a list of departments or schools of music connected with universities. In all of them practical and theoretical courses are given.

UNIVERSITY	TITLE	FOUNDED	DEGREES	EXPENSES (TUITION AND BOARD)
Northwestern University, Evanston, Ill.	Department	1873	B A. & M A., since 1895	\$300-\$600
Michigan University, Ann Arbor, Mich.	School	1873, reorganized 1890	B A.	\$15-\$90 a course
Oberlin, Ohio	Conservatory	1867	Mus. B and Teachers' Certificate	\$350-\$500
Grinnell College, Grinnell, Ia.	School	1875	B.A.	\$300-\$430
Wisconsin University, Madison, Wis.	School		Mus. Grad.	
Syracuse University, Syracuse, N.Y.	Department	1873	B M. and Certificate	\$325-\$500
Illinois University, Urbana, Ill.	School	1895	B.M.	\$280-
Boston University, Boston, Mass.	Course		B A.	
Pennsylvania University, Philadelphia, Pa.	Department	1875	B A ; Mus Bac.	\$30 a course

Boston, Mass., New England Conservatory of Music. — Founded in 1853 by Eben Tourjee, and incorporated in 1870; one of the best equipped schools in the world, owning one

Music Departments in Colleges for Women. — Wellesley College, Wellesley, Mass. — No credits are given for music in entrance requirements. Courses in theory and history are open to all students, and count toward the A.B. degree. Practical courses are given in piano, organ, violin, and voice and theory leading to B.A. The length of the course is from four to five years. Special students are admitted, and may receive a certificate of the Department of Music. The expenses for tuition in practical music and board in halls of residence is \$450 per school year.

Smith College, Northampton, Mass. — Courses in music may be taken in connection with regular college work, and count toward the degree of B.A. Music may count as one point of credit in the entrance requirements.

Vassar College, Poughkeepsie, N.Y. — Only regularly enrolled students can elect studies in the music department, which may count up to one fifth of all studies required toward the degree of B.A.

Independent Conservatories and Schools of Music. — These have become an important factor in the musical development of America. Every large city has a number of schools comparing favorably with the best schools in Europe, and there is hardly a town which does not support a school of music of its own. Only the most important are mentioned here.

Baltimore, Md., Peabody Conservatory of Music. — Founded in 1868 as a branch of the Peabody Institute, established in 1857 by George Peabody. All branches of music are taught in two main departments: Preparatory (elementary, junior, and intermediate); and Conservatory (advanced, senior, and graduate). There are about 1400 students and 60 teachers. Tuition fees average about \$125 a year.

of the finest buildings for the purpose. The conservatory possesses, besides a large number of studios, two concert halls, a splendid library, a collection of instruments, eleven pipe organs, etc. Complete courses are offered in all branches of music. Candidates for graduation must have been graduated from a high school or must take work in literature. Privileges are interchanged between Harvard University and the conservatory for qualified students. The university credits certain conservatory courses toward the A.B. and M.A. There are about 2700 students, with ninety instructors. The average cost of tuition for the full course per school year is \$250.

Chicago, Ill., American Conservatory of Music, 1886. — A school with a faculty of seventy-five teachers and an attendance of over 2000 students. All branches of music are taught, enabling a student to become a practical and theoretical musician. The regular course requires from three to four years of study. After successful examinations graduate and post-graduate diplomas are issued. Special features are normal classes for teachers, a children's department, and a students' orchestra. Deserving students are given scholarships at the discretion of the board of directors. Tuition from \$10 to \$160 per term of ten weeks.

Chicago, Ill., Musical College. — One of the oldest private schools in the country, founded in 1867. Its organization is similar to that of the American Conservatory of Music, without some of the special features mentioned. There are about 100 teachers and 3000 students. Among the teachers have been some of the best known European musicians.

Cincinnati, Ohio, College of Music — Founded in 1878 by Reuben R. Springer, with Theodore Thomas as the first director. All

MUSIC IN EDUCATION

branches of practical and theoretical music are taught by about forty teachers. The number of students is 650. Certificates and diplomas are granted after successful examinations. Special features include a school of opera, a students' orchestra, and a students' chorus. Tuition varies according to instruction selected.

New York, N.Y., Institute of Musical Art. — Incorporated 1905 under a charter granted by the board of regents of the University of the State of New York. It has an endowment of \$500,000, given by James Loeb. There are seventy teachers and 600 students. Certificates and diplomas are granted in all branches of music study. The tuition per school year varies from \$15 to \$250, according to studies selected.

Other important schools of music in New York are: National Conservatory of Music; German-American Conservatory; Virgil School of Music; Guilmlant Organ School.

Philadelphia, Pa., Combs Broad St. Conservatory of Music. — Complete courses are given in piano, violin, vocal, hand, and orchestra instruments. The following sections are maintained: introductory; advanced; teachers'; diploma; postgraduate; and artists', leading to the degrees of M.M. and B.M. Reciprocal relations are maintained with the University of Pennsylvania, which offers to music students English, French, and German, upon passing satisfactory examinations for admission to college in the subjects chosen, while the university gives full credits for theoretical work done at the conservatory. Tuition from \$40 to \$200 for the school year of forty weeks.

MUSICAL INSTRUMENTS, MECHANICAL, AND EDUCATION. — Visual aids (*q.v.*) to teaching have long been used in almost every subject and in greatest variety. Auditory aids have not been available until within the last few years, when remarkable inventions have provided such means. These auditory aids consist of the variety of mechanical musical instruments such as the phonograph and similar instruments for reproducing sounds and the pianola and similar mechanical devices for operating pianos. A third type represented by the Welte-Mignon is just being developed which provides for the actual reproduction of the interpretation of a virtuoso or of any individual performer. These three types differ radically in their nature and in the kind of educational opportunity they offer. The first type, by some contrivance of disks,

grooves, and vibrating keys, reproduce more or less accurately and with mechanical fidelity any kind of musical sound, including the human voice. The second type operate mechanically the piano and thus produce only one type of music, but that with the instrument of widest musical scope. These latter furnish the technique of the performance, but allow to the individual operator room for the variety of expression and interpretation which renders music an art.

But little use has been made of such instruments in the school, and but slight recognition has been aroused until the last few years. It seems no exaggeration, however, to state that they promise to do for musical education what the various arts of illustration have done for painting, and the art of printing itself has done for general intelligence. The first great educational service which such inventions, especially those of the pianola type, seem to furnish, is that of making musical appreciation as common as the art of printing has made our appreciation of literature. Not only this, but by means of the voice-reproducing instruments, productions artistic both as regards tone and delivery can be given in the schools, thus teaching by excellent examples and employing methods especially essential in the lower grades. There is no reason why a knowledge of the finest music should not be considered an attribute of culture as well as a knowledge of the best literature. Long ago a German educator said: "The fundamental evil in music is the necessity of reproduction of its artistic creations by performance. Were it as easy to learn music as words, the sonatas of Beethoven would have the popularity of the poems of Schiller." And little reason exists why in a coming generation an ability to reproduce the best music with fidelity and artistic expression should not be within the power of any educated person. It seems no exaggeration to say that what printing did for general intelligence, some of these inventions promise to do for artistic appreciation. For by means of unlimited reproduction, which such instruments afford, the same advantage is given as by the printed page. For some generations now a recognition of the place of music, especially of musical appreciation, in education has been growing, and many attempts have been made both for children and adults to develop such power of appreciation or performance. But aside from singing, these efforts have been limited, especially with English-speaking peoples, to adults. Here it has appealed chiefly as an expensive pleasure, limited to a favored few. Now, these mechanical devices remove the difficulty of technique and afford the means of repeatedly reproducing the entire subject matter of music, and of giving the child or operator the pleasure and training of participating in this reproduction. Even with the favored few possessing a musical education, a

large part of the world's musical treasures are practically a sealed book, a book which may in time, if the real educational value is obtained, be opened to all.

The talking machine has now become an important part of the equipment of the schools of perhaps 500 or more cities throughout the country. So rapidly has this innovation taken place that few realize the tremendous hold that music has upon people, and the avidity with which educators have seized upon this really wonderful invention, which brings to every child the hearing of the great music of the world. Special records for teaching purposes, in all grades,—folk dances, interpretative dances, folk songs, songs of different nations to correlate with the work in history, records showing the tones of all the instruments of the orchestra,—are now to be had. A course of study for high schools in history and appreciation, using several hundreds of records from the operas, oratorios, etc., has been published. These courses of study, copiously illustrated by splendid reproductions of the voices of the artists, carry into the school-room the culture and knowledge of real music, and must prove a boon, especially to the rural, village, and small city schools, where the children never have an opportunity of hearing the great artists, orchestras, and the opera.

It is to be hoped and expected that the schools will soon avail themselves more generally of these inventions and that music may be given a place in American and English culture as a social, moral, and æsthetic agency of vast import as it has long been in some other civilizations.

A second service which the piano player affords is of a more technical character in the beginnings of instruction in piano playing. But as the most comprehensive of all instruments and the one in most general use, this service may be of no slight character, though musicians are more divided or much less enthusiastic in their beliefs as to what mechanical invention can do here than in the cultivation of musical appreciation in general. With the mechanical piano player it is possible to carry any parts of the composition by mechanical means, while the learner may develop his ability to play other parts of progressively greater difficulty. That is, a pupil can play a five-finger exercise and at the same time so operate the instrument with his feet that interesting harmonies will be produced. One marked advantage which this scheme has is that of having the child work on pieces of inherent merit and attractiveness which otherwise would be too difficult for him to attempt. Possessing both advantages and disadvantages which are obvious, this use of the piano player has not been sufficiently tested to enable musical educators to form a judgment.

While the use of the piano player as an aid to musical instruction has had but slight use

in the public school, it has been recognized quite generally in American colleges and universities. Not only are these instruments used in many of the institutions as a means to musical education of students, but the professors of music of Columbia, Harvard, Michigan, Oberlin, Smith, Tufts, Vassar, and leading professional musicians have cooperated with the manufacturers in working out elaborate courses in the music of the greatest composers, such as Bach, Beethoven, Chopin, Liszt, Schumann, Wagner, and others as a means to a general cultural education. These courses combine lectures and interpretation with selections.

Thus the general public can obtain real insight into great music by means of actual auditory illustration and expert comment. It is the hope of these educators that in time music may cease to be a special cult, as unfortunately it is in our civilization, and become a matter of common culture depending, as do other elements of culture, not upon a highly technical ability but upon the intelligence and sympathy of the individual.

MUTISM.—The inability to speak, due to lack of cerebral development (in idiots), to sensory disorders (as in deafness), or to inhibition or negativism (in dementia precox, *(q.v.)*), or in hysteria (*(q.v.)*). The acquired mutism is to be distinguished from aphasia (*(q.v.)*), in which the ability to speak has been lost. Mutism is simulated by the apparent

lack of speech in melancholia (*(q.v.)*) in which there is mental and motor retardation. The inability to speak following emotional excitations, *e.g.* fear, are normal conditions. Like mutism they are frequently found in children, especially in those of nervous temperament, and they are often the first symptoms in the development of grave psychoses, *e.g.* dementia precox, hence their importance in education.

Deaf mutes may be educated to use the vocal apparatus, and the absolute mutism may be replaced by speech. There is, however, an incoordination, for the sounds lack the modulation to be found in the voices of normal people. This is because of the inability to correlate the sounds with the movements of the vocal apparatus. Mutism in idiots is incurable, but the mutism of imbeciles may, by appropriate education, give way to a vocabulary sufficient to indicate their wants and desires. The mutism in melancholia is only temporary, and disappears with the improvement in general condition. The dementia precox mutism is also temporary, and may be improved by stimulation and by appropriate training to a slight extent, but the amount of improvement depends upon the accessibility of the patient.

MYOPIA (from late Greek *μυωπία*, from *μύω*, from *μύειν*, to shut, and *ὥψ*, sight), or more scientifically BRACHYMETROPIA or BRACHYOPTIA (from *βραχύς*, short, and *ὥψ*, sight).—That condition of refraction where the antero-posterior diameter of the eye is too great and parallel rays of light entering the eye at rest come to a focus in front of the retina. This defect has now been studied in the eyes of hundreds of thousands of school children; and as a result of the modern investigations the following facts have been pretty well established. There are two kinds of myopia: (1) myopia of high degree, a disease of degeneration more likely to be found among the lower classes; (2) myopia of low degree, the common form, known as functional, frequently not appearing till puberty. It is not a disease, but a defect. The distinction between the two forms was recognized by Dr. Beger in a monograph on nearsightedness, published in 1845.

The question of the cause of myopia is still a much-debated one. Those who agree with Cohn hold that the school with its unhygienic conditions of work is the chief cause and point out that in Germany not only the number of cases but the degree of nearsightedness increases

with the age and grade of the pupils. More recent investigations (*e.g.* by Steiger, Miss Barrington, and Karl Pearson) seem to show that myopia, as well as other errors of refraction, are inherited. On another point, also, modern opinion has changed, modern studies showing that the defect of myopia occurs among primitive as well as among civilized people. The most prominent recent theory on the subject has been formed by Stilling, who on the basis of many thousand measurements of the cadaver, maintains that myopia is caused primarily by innate structural peculiarities of the eye socket, and that those who have a low orbit have a tendency to myopia. The practical result of such a theory, on which a controversy has raged for twenty years, would be to make it possible from the shape of the skull and the orbital index to pick out on the first day of school those pupils who have a tendency to myopia and to relieve them from the strain of near work and later to determine the kind of vocational training for which they are fitted.

In no part of the field of school hygiene, perhaps, have more errors prevailed than in this particular chapter. And among the many investigations that have been made during the last hundred years it is possible to find statistical evidence for almost any current error. Not only the teacher, but the specialist himself must be on his guard against being misled by the results of so-called studies of this subject.

Perhaps the best way to summarize important points, and to show briefly the complexity of the problems connected with the genesis and development of myopia and the danger of hasty inferences, is to enumerate some of the errors that have prevailed and still survive in some quarters. Among these are the following: 1. The error of not distinguishing the different conditions of refraction and of confusing weakness of vision from whatever cause with nearsightedness, *e.g.* the cases of hyperopia, myopia, and presbyopia. 2. Even scientific writers often fail to distinguish between pathological myopia and ordinary myopia, which is merely a defect. And even to-day the usual form of myopia and the pathological form are often not distinguished. 3. Some writers like Cohn have believed that the ordinary myopia may develop into the pathological form. The two, however, are distinct, and it seems probable that the former never develops into the latter. In the pathological form, as Stilling puts it, the eye is not diseased because it is myopic; but it is myopic because it is diseased. 4. The error still prevails that myopia is caused by the conditions of civilized life, whereas it is found among primitive peoples as well. 5. The charge is still made even by scientific writers in an indiscriminative way that the school is the cause of myopia. Studies by Steiger have shown, however, that not only do cases of

myopia occur at the time when children enter school, but that among nearsighted children the percentage of cases of myopia of high degree is enormously greater than among children who develop nearsightedness later, say at the age of twelve. The pathological form of myopia at least would develop in any case whether children attended school or not. Landolt, Hoor, and others have found myopia of high degree among peasants and soldiers, people who never used their eyes largely for near work, and who never had attended school. 6. The error of supposing that because the number of cases of nearsightedness, especially in Germany, is apt to increase from the lower to the higher grades, the school is responsible for this increase. This inference, plausible as it seems, is not justified by the evidence cited. Not only are many cases likely to develop at the age of puberty, apparently on account of the conditions of growth, but no account is usually taken of the fact that children who are myopic, lacking an interest in outdoor occupations on account of their imperfect vision, are more likely to become interested in school work, and hence more likely to remain to the higher grades of the school. 7. The error is widely prevalent that myopia is caused primarily by near work, whereas it seems to have been amply demonstrated by the studies of Motais, Steiger, Miss Barrington, and Karl Pearson that errors of refraction are inherited. And while the use of the eyes for near work is probably a secondary cause determining largely the development of the defect, it is not the primary cause. 8. The error of supposing that the conditions of the human eye at birth is myopic. This error was due in the first place to the old investigations of Jaeger, who by some erroneous method found that most of the cases of newborn children studied by him had myopia in some degree.

A number of interesting correlations have been strongly suggested, if not established, by modern studies, among them the following: a correlation between the number of cases and physiological development; between the tendency to myopia and sex, girls being apparently more likely to become myopic; between the number of cases and the general environment, the percentage of cases being often greater among the children of the well-to-do; between the percentage of cases and the intelligence of the pupils and their success in school work, myopia occurring more frequently apparently among the more successful pupils; and a correlation according to the shape of the skull, the brachycephalic being prone to myopia. It is also maintained by some that there is a correlation between the number of cases and the degree of civilization in a country, and likewise between the number of cases and the hygienic condition of the schoolhouse and school environment.

Very extreme views have been held by some of the leaders of the controversies waged in regard to myopia. On the one hand, Schnabel and others have maintained that myopia is a good thing, that it means the perfection of the eye for the finer occupations and near work required by civilized life; while on the other hand are those who have taken an extremely pessimistic view and taught that myopia is a disease, that all are liable to the defect, and that all cases are liable to develop into the pathological form.

There are many unsolved problems in regard to myopia, and further studies are needed; but those who would learn the present condition of our knowledge in regard to this defect should be suspicious of the popular writings, and consult among investigators, not Cohn and the older writers, but rather Steiger and Karl Pearson.

While the net result of modern investigations has been to show that heredity is the primary cause of myopia, that it is probably in large part due to innate structural peculiarities of the eye, and that the school and near work are only in a secondary way responsible, these results do not make the demands of hygiene less important. While it may be quite impossible to prevent the development of myopia, it is a significant fact for hygiene that probably from ten to twenty-five per cent of the children in any school are likely to have this defect or else a tendency to it, and it is necessary to make the conditions hygienic for such myopic eyes. They should be tested by competent oculists, fitted with suitable concave lenses, the error of refraction fully corrected, and the ordinary well accepted rules for the hygiene of the eye should be observed. MYSTICISM. — Mysticism is that type of religion in which the soul endeavors to apprehend eternal realities immediately by an inner experience. It places little emphasis upon rites as a means of influencing the deity or of obtaining power and sanctity, or upon obedience for the sake of rewards, but it endeavors to obtain a present enjoyment or foretaste of eternal bliss by a suitable training of the soul. Together with the sacramental idea, mysticism is present as a normal religious phenomenon in many higher forms of religion, especially those in which asceticism is developed. In primitive Christianity it finds its expression in the New Testament in the writings of Paul and John. Although the name mysticism is taken from the Greek mysteries, it was long before they had any influence upon Christian mysticism and early resemblances cannot well be explained upon any theory of borrowing. In Christianity mysticism took two distinct lines of development, a more emotional and a more speculative. In the East the former is seen in Ignatius of Antioch (*ob. c.* 115) who first developed the Johannine tradition, then in Irenæus, Methodius, and Athanasius, and, in a somewhat different form and more strongly influenced by contemporary Hellenic philosophy in Clement of Alexandria and Origen. In the West this Mysticism found its first great exponent in Augustine, who in his *Confessions* passes far beyond any Neo-Platonic mysticism he may have retained; for however much Neo-Platonism influenced Augustine's doctrine of God and of evil, his mysticism, anticipated somewhat by Ambrose, has a different content and establishes a new type of piety. Its influence upon Western thought appears again most impressively in Bernard of Clairvaux in language which recalls both the rapture and the diction of the *Confessions*. The principal source of speculative Christian mysticism is the works of the Pseudo-Dionysius the Areopagite, written under the unmistakable influence of Proclus the Neo-Platonic philosopher. These works were written about the end of the fifth century, purporting to be the writings of the Athenian convert of St. Paul, and accepted generally as such they profoundly influenced religious thought. Their authenticity is now defended by no scholar. The Areopagite took over the Neo-Platonic metaphysics of his master and his practical method whereby the soul after passing through stages of purification, illumination, and completion became one with the primordial being. These three stages

reappear in all systems of the Christian mystical theology. In thus adapting Neo-Platonism to Christian mysticism, the Pseudo-Dionysius considerably Christianized it and Maximus, the Confessor, who wrote a commentary upon Dionysius, carried the process still further. The influence of the Areopagite in the West dates from the ninth century and John Scotus Eriugena, who built for himself upon him a system of pantheistic mysticism.

After the introduction of Dionysius the Areopagite into the West, mysticism, except as the pious experience of saints such as Anselm of Canterbury and Peter Damiani, plays no prominent part until the development of mystical theology in the twelfth century under the general intellectual revival of that age. From the first in this revival both types of mysticism are clearly developed and in the closest connection. Hugo of St. Victor (1078-1141) is the first after Eriugena to comment on the Areopagite and also the first of the greater mystical theologians, tracing clearly and successfully the foundation of mystical theory and basing it upon a psychological analysis of man's religious nature and mental and moral powers. After him Richard of St. Victor (*ob. c. 1174*) and Bonaventura (1221-1274) develop the system, building upon the foundations laid by Hugo. With these three the theory of mysticism as worked out in the Medieval Church is complete. The metaphysical and psychological basis of this theory always remains strongly tinged by the Neo-Platonism of the Pseudo-Dionysius and the connection can always be traced. But the theory is by no means merely metaphysical; there are always two ways of attaining the goal of mysticism, an ethical and an intellectual, which are only different sides of the same process; for to know anything one must share in its nature. In this lay the basis for the union of the various types of mysticism into one general theory. It, too, was derived from Neo-Platonism.

The significance of mysticism for pedagogy is that in it, by an analysis of the soul's life, a psychological basis was won for a religious pedagogical theory which corresponded to the ideals of life of the times. This theory is not worked out systematically in any one treatise, not even in Hugo's *Eruditio didascalica* or *Didascalicon de studio legendi*, the most important educational treatise written by any of the medieval mystics, but it underlies a great mass of ascetic and devotional literature and is not difficult to grasp. This pedagogical theory corresponds to the monastic ideal of life, which till nearly the time of the Renaissance was dominant in Western Europe. Monasticism as it was organized by Benedict, and even as it was reformed under the influence of Cluny, provided little more than the outward conditions for the higher religious life, and it was only in and through mysticism that

monasticism received its higher pedagogical principles and was brought into vital relations with the intellectual movements of the age. While scholastic theology was a practical science, mystical theology had always a practical end, a pedagogical purpose; for in tracing the stages of the soul's advance to higher spiritual experiences and to the end of all, union with God, it provided means for a systematic training of the whole spiritual nature. In its Areopagitic form mystical theology revealed a religious content and significance in science. This is clearly brought out in Hugo's *Eruditio didascalica*, to which the other mystical and theological works of Hugo form a useful supplement. In form the *Eruditio* is in imitation of the encyclopedic works of Isidore of Seville, Hrabanus Maurus, and others, a comprehensive survey of the various profane and sacred sciences (See HUGH OF ST. VICTOR.) A pedagogical theory, which aims at the cultivation of the purely spiritual functions, comes into close contact with the science of the times; in fact, brings it into its system.

However much the intellectual side of mysticism might be emphasized in a work which professedly treated of the method whereby science might be used in mystical training, the ethical side is as essential to mysticism as it was to Neo-Platonism and was closely connected with the cogitative process and the way of purification. It is only less psychological, and is more ascetic and devotional. The soul approaches God by purification of the heart; for one sees only as he is what he sees. In the case of God, he can know God only as he loves God. Therefore, by ascetic training a man frees himself from the external world and the life of the senses, with its passions and desires. He is trained in virtue, and here mysticism and theological ethics are one. This training differs from the popular ethics in being a preparation of the soul rather than a means of acquiring merit. The soul, thus prepared by ascetic discipline intelligently directed, and by meditation upon the facts of divine redemption, attains the same result as in the intellectual training, which it must always accompany. In perfect union with God, the soul loves nothing less than God, loves all else than God only as they are seen to be included in the love of God.

In the hands of Bernard (*q.v.*) who joins it indissolubly with the monastic asceticism, mysticism obtained a power of conviction which left a permanent impression upon Western religion. It does not lend itself to any appropriation of contemporaneous science; it cannot be formulated in a pedagogical theory, but it can be easily detected as reinforcing the emotional side of mysticism which was in danger of being lost in an intellectual process. It was of special value in the religious training of the age in revealing higher forms of sanctity attainable by those

who were not adepts in speculation. Even laymen, especially those who were affiliated with monastic institutions, came to have a place in the new training designed primarily for monks. This is especially clear in the later mysticism of Germany. On account of the ascetic character of mystical devotion, mystical writings are commonly classed as ascetic writings. They have never ceased in the religious world. The most remarkable of works of devotion and courses of spiritual training, the *Spiritual Exercises* of Ignatius of Loyola, is essentially a work of mysticism, and the methods of the Victorines and Bonaventura are manifested throughout it.

Only medieval mysticism is of special pedagogical significance. It alone corresponded to the ideals of the times. In the later Dominican mysticism, popularly known as German mysticism, there is little distinctive that needs to be noticed. Notwithstanding Eckhart's departure from orthodoxy, he stands for the most part upon Thomas Aquinas. He and Tauler, together with several others, differ from the older mystics principally in extending their work beyond the monastic life and by writing in the vernacular. This later mysticism, although the little treatise *Theologica Germanica* was highly esteemed by Luther, is not to be regarded as leading the way to the Protestant Reformation. Its spirit is distinctly medieval.

Mysticism in the West is by no means confined to the Medieval Church. It constantly appears in Protestantism, to mention only in German the theology of Luther and Pietism, in the Anglican Communion, the mysticism of Andrews, Wilson, and Law and the rich hymnody of the Wesleys. How widespread it is in Protestantism William James shows in his *Varieties of Religious Experience*. In Protestantism mysticism is Augustinian, rarely Areopagitic. In the modern Roman Catholic Church, mysticism has taken a new development, especially in the hands of Görres. In his treatment, the whole mass of "mystical" phenomena is classified and the miraculous element, little emphasized by earlier mystics, is stressed. Accordingly, mysticism is regarded as a higher knowledge made possible by an imparted higher light and a higher, i.e. miraculous, activity made possible by an imparted higher freedom, in the same way that ordinary knowledge and activity are possible by the light and freedom implanted in the soul. This explanation, established by a novel analysis of the spiritual and mental faculties, gives an interesting explanation of the miraculous, sees a new and wider scope in mysticism which is recognized as a widespread religious phenomenon, and distinguishes between true and false mysticism, formerly a difficult matter. True mysticism, accordingly, is that in which man actually stands in relation to God and this is possible only when in his

ordinary religious consciousness he holds the right conception of God. But in all these modern developments, wherever they appear, mysticism has departed from the pedagogical point of view which it may be said to have had in the Middle Ages as a method of spiritual training.

MYTHS AND MYTHOLOGY.—Definitions.— Mythology may be said to be the prehistoric form of existing religions, just as superstitions may be termed the survivals of otherwise extinct beliefs. Religious feeling of some sort is common to all mankind, but it has not developed equally or in the same direction among every people. It keeps pace in general with the advance of civilization and material prosperity. The term mythology has been applied to that form of belief which has been developed especially under literary influence, while religion commonly denotes the serious belief of peoples as represented by the Church, and superstition means the semi-conscious beliefs handed down from generation to generation by word of mouth.

Each of these has its special devotees: the poets love to dwell in mythological realms, the philosophers explore the field of religion, while the common people hold firmly to their superstitions. And all of these things have probably been as true for thousands of years

as they are now. Any given legend, doctrine, or superstition may usually be readily traced back for centuries among the various peoples having a historic past; and the same is doubtless true for the others without a known past history.

A myth is some particular religious legend considered by itself, and hence it is the unit from which mythology is constructed. It usually belongs in its most perfect form to a rather primitive stage of development in the scale of civilization, as in later times it is apt to become merged in a confused mass of tradition. It should further be observed that in a restricted sense and as commonly employed the term "mythology" denotes the legends told by the ancient Greek and Roman writers concerning their gods and heroes, and since their day perpetuated by literary men in all the nations of the modern civilized world.

Theories.—Various theories have from time to time been advanced by scholars to account for the origin of myths and legends. Some have tried to see in them attempts at popular etymologies, by which process some fanciful tale was invented to account for an epithet commonly applied to some deity. Such stories are best exemplified in the *Metamorphoses* of Ovid, whose popularity has always been deservedly great. Others have wished to account for their origin by referring them back to the great natural phenomena which were thoroughly appreciated in all their grandeur by early peoples. This theory has of late years been in special favor with the modern school of anthropologists. Still others would have it that they are but a generalization and idealization of ordinary human activities and attributes, thus offering a wholly rational explanation of a common mental phenomenon.

In all cases of theorizing, however, it would seem to be highly important to compare the mythologies of various nations in all stages of civilization in order to gain a broader view of the whole field than would otherwise be possible. This special phase of the subject is denominated Comparative Mythology.

Greek and Roman Mythology.—In the Golden Age of Greek and Latin literature, which we commonly call the classical period, the old religious beliefs had lost their hold on educated men, and thus it came to pass that the poets of the time were wont to relate the old mythological stories in a half credulous fashion which was fortunately well adapted to their artistic purposes. And indeed mythology was so closely interwoven with the whole of classical civilization that it would have been impossible for any one entirely to free himself from its influence.

With the coming of Christianity and its rapid spread throughout the Roman Empire, the old mythology was relegated more and more into the background. It was afterward perpetuated during the Middle Ages solely by

the efforts of literary men, until at the time of the Renaissance its cultural influence became very strong, especially so in Italy. In more modern times mythology has once more waned in popular estimation, being driven out more and more from the public consciousness by the constantly increasing rôle played by science. Only in the realms of art and literature is classical mythology still an important factor.

Celtic and Teutonic Mythology.—There is, however, another influence in modern Europe, whose mythological power is great; namely, the traditions of the Celtic and Teutonic peoples, whose ancient beliefs still form an essential part of our intellectual life. The former is as beautiful and graceful as the Greek, and it possesses an immense poetic power, with its direct appeal to the imagination; the latter, with its crudeness and stern warlike note, gives stamina to our being, and fosters the more practical qualities that have built up Anglo-Saxon civilization. For English readers the Celtic gods and heroes are the natural inhabitants of a British landscape, especially so in the wilder and more mountainous western section where the original inhabitants of the land lingered longest. Thus, in the west of England, in Wales, in Scotland, and especially in legend-haunted Ireland, the hills and dales still keep memories of the ancient gods.

Teutonic mythology is closely akin to great natural phenomena in their earliest attainable form. But as civilization began to exert an appreciable influence on the Northern peoples, it was profoundly modified both by the process of internal development and by the external force of the Christian religion. At the present day the old mythology has among the educated classes been relegated largely to the nursery; but among the common people its influence on their religious beliefs is still powerful.

Uncivilized Mythologies—A great deal of attention has been paid of late years by anthropologists and students of folklore to the religious beliefs of semicivilized, barbarous, and savage peoples; and a vast amount of material bearing on this subject has been gathered up, chiefly from oral sources. Investigations based on such material are of great importance as showing the workings of the human mind in the religious sphere, and as throwing a strong light on the prehistoric phases of our own beliefs.

Mythology had its birth, unquestionably, among uncivilized peoples. There we find that when the mind is fresh the mythical fancy has its creative hour, and develops the most varied and fantastic forms; and these manage to perpetuate themselves long after their original significance has been outgrown and forgotten. Thus we see that the myth-making tendency is strongest, and exerts its

most effective influence, when a race is passing through its formative stages such as are well represented in the savage races of the present day. Every student who attempts to penetrate back to the sources of a civilized people's religious faith will find himself surrounded by a luxuriant growth of mythological legends which may seem weird and strange to him merely by reason of their remoteness from the mental life of modern times.

In the western hemisphere the European races have during the last few centuries been brought into direct contact both with the legends and beliefs of the aboriginal Indians and with those of the negro races in the persons of the numerous slaves imported from Africa. As modern civilization has inevitably influenced both of these subject races (the former but slightly, the latter profoundly), there is presented to us the rather curious phenomenon of the forcible grafting of one system of mythology upon another older and more primitive system; just as in England the Teutonic mythology was superimposed within historic times upon the Celtic mythology of the subjugated inhabitants who had previously been politically supreme in the island.

Mythology in Schools. — Of late years there has been considerable discussion in educational circles as to the relative value of history and mythology in the curriculum of the schools, — of the facts of the past and of its legends. The extensive literature which has received its chief inspiration from myths of all sorts, the many classical dictionaries and textbooks on the subject, all bear testimony as to its importance as a study.

In the use of mythology for this purpose it is of the utmost importance to approach the subject in the proper spirit, and to bear in mind the particular needs as well as the stage of mental development of the class to be instructed. Take the story of Arachne, for instance. It may be used with very young children as a nature myth, explaining in an interestingly dramatic way the origin of the spider and its peculiar characteristics. Used with older children, however, and emphasis being laid on Arachne's pride and willfulness, the same myth can be just as profitably employed to accomplish an ethical lesson. The same story with grammar-grade pupils might also be treated as a bit of historical material, showing how early man blended his religion and the nature world. Or again, consider the Tyrolian legend of the origin of flax, which will serve to illustrate the many-sidedness of myths and their adaptability to the various other studies of the child. This story, used as a character study in a reading or language lesson, may be correlated with the study of plant life in science, or with the consideration of raw products in geography; or in history it affords a poetic explanation of the beginning of one of Europe's greatest industries.

To use a myth primarily for a reading or language lesson would not be very purposeful. The most important use of myths at any time is to furnish thought food for that particular period of the child's development. Indeed, it is contended by many educators that history proper appeals only to the understanding, but that mythology, with its attractive legends, stimulates the imagination of the pupil; and that the one study is as essential in the development of the student's mind as the other.

NAGEL'S TEST.—Nagel's test for color blindness and lesser defects in color discrimination is doubtless the best simple test yet devised. It is specially valuable in testing large numbers of persons quickly (railroad, army, and navy service). It consists of two sets of small cards on each of which there is printed a series of colored dots, each about 4 mm. in diameter, arranged at equal distances on the circumference of a circle. The principle of the test is, of course, to give the dots on each card colors peculiarly likely to be confused, or perceived as identical in color, by the color defective. The first set has sixteen such cards; these are spread out on a table before the subject, in good daylight, and he is then to view them from a distance of about $\frac{1}{2}$ m. (since the dots should be seen in foveal vision) and indicate, first, all cards possessing reddish dots and, second, all with only reddish dots. The same procedure is then repeated for green and gray. By following the brief but adequate directions accompanying the cards, any experimenter of reasonable intelligence may, by this first set of cards, in a short time eliminate from a number of subjects the color defectives. The second set of four cards is designed to determine the particular type of color defect present. It has been found that the average person may be tested in less than two minutes.

The charts of Stilling may be used as preliminary test; they do not, however, give certain results. On a sheet of nearly uniformly colored dots there are intermixed others, in colors likely to be confused with these, arranged in the form of a letter or an Arabic

numeral. The subject is required to decipher the letters and numerals on the various test sheets. Holmgren's test (*qv*), or some modification of it, and Stilling's and Nagel's tests are probably the three most used for the testing of color vision for practical purposes. Of these the best is Nagel's. For more detailed laboratory investigation one should have recourse to Hering's tests or to the spectral color mixer. For descriptions of these the literature of the subject must be consulted. R. P. A.

NÄGELI, HANS GEORG (1773-1836).—Composer and teacher of music, born in a village of the canton of Zürich. He studied at home and at Zürich, where he later opened a music store and lending library, and gave music lessons. In 1800 he issued a periodical dealing mainly with music. In 1810 with M. T. Pfeiffer he published *Die Gesangbildungslehre nach Pestalozzischen Grundsätzen* (*Theory of Instruction in Singing on Pestalozzian Principles*). This work had considerable influence on the introduction of singing as a regular school subject both in Europe and the United States, where the work was introduced by Lowell Mason (*q.v.*) and W. C. Woodbridge (*q.v.*). See *Music*.

NANCY, UNIVERSITY OF, FRANCE.—

The University of Nancy is the direct successor to the university established at Pont-à-Mousson by Papal Bull of 1572 on the petition of Duke Charles IV of Lorraine and the Cardinal of Lorraine. At first only the faculties of theology and arts were organized and placed in the hands of the Jesuits. In 1582 the faculty of law was established and in 1598 the faculty of medicine followed. The university met with great success and, with the college or secondary school, numbered 2000 students, the majority in theology. The Thirty Years' War and the subsequent wars of that century put an end to the progress of the university. In the eighteenth century the dukes of Lorraine, especially Duke Stanislaus, aimed to promote higher learning at Nancy. He established a public library, an academy, and a medical college. In 1768 the university was transferred from Pont-à-Mousson to Nancy and continued there until the time of the Revolution (1793). It was not reestablished in the reorganization of Napoleon. A

medical course was, however, conducted privately from 1822 to 1843, when it became the *École préparatoire de Médecine et Pharmacie*. In 1854, as a result of a public appeal, the university was restored with faculties of letters and science; in 1864 the faculty of law was established; in 1870 the School of Medicine became a faculty. The Franco-Prussian War drove many members of the University of Strassburg (*q.v.*) into exile; many were welcomed at Nancy and the whole medical faculty was taken over in 1876. In addition to the four faculties there is also an *École supérieure de Pharmacie*. The enrollment in 1911 was 2184 (law, 491; medicine, 440; science, 793; letters, 402; pharmacy, 58). The following institutions at Nancy, some conducted by members of the university faculty, some independent, may be mentioned: *École Nationale des Eaux et Forêts*; *Institut Chimique*; *Institut Electro-technique et de Mécanique Appliquée*; *Institut Agricole*; and the *Institut Colonial*.

NANTES, SCHOOL OF MEDICINE AND PHARMACY. — See above.

NAPIER, JOHN, BARON OF MERCHISTON (1550–1617). — Scottish mathematician, commonly known as the inventor of logarithms (*q.v.*). His name appears in various forms, as Neper, Neperus, Naper, Napier, Napeir, and Nepier. He matriculated at the

first published in 1614 under the title *Mirifici Logarithmorum Canonis Descriptio*. D. E. S.

See LOGARITHMS; NAPIER'S RODS.

NAPIER'S RODS. — In 1617 Napier (*q.v.*) published at Edinburgh a work entitled *Rabdologia, seu Numerationis per Virgulas, libri duo*, in which he set forth a scheme of multiplication and division by means of rods marked as shown in the accompanying illustration. As arranged by Napier each rod was a parallelogram with an angle of 45 degrees, although those usually sold at present are rectangular in form. In the illustration here given, one of the rods is shown with the number 7 at the top, and the products of 7 by the various digits below. A group of rods is also shown giving 734 at the top. If we wish to multiply this by 568, we can at once read off the partial products, so that all we need to do is to arrange the rods as shown, write down the partial products, and add.

Since the rods were at first made of bone, they are often called Napier's Bones. They never had any extensive use, but they can still be purchased from certain dealers. As a school device they add a little to the temporary interest of the pupils, but their value ceases here.

D. E. S.

NAPLES, UNIVERSITY OF. — Founded in 1224 by Frederick II, who forbade his subjects to attend any other institution for higher

University of St. Andrews in his thirteenth year. Little is known of him, however, from that time until the publication of his strong anti-papal *Plaine Discovery of the Whole Revelation of S. Iohn*, which appeared at Edinburgh in 1593 (second edition, with the title as here given, 1611). He seems about this time, or at any rate by 1594, to have been occupied with his plan of simplifying numerical calculations, particularly those that enter into trigonometry. His logarithmic tables were

learning. Unlike the other universities of the period, the University of Naples was thus established by decree of a monarch before there was any organization of studies or students. The institution met with very little success and was in abeyance and "reformed" several times before it began to show signs of prosperity under the encouragement of Charles of Anjou and Pope Clement IV, who reorganized it in 1266 with all the faculties, including medicine and theology. In the last-named faculty

Thomas Aquinas was for a time lecturer. Another feature which distinguished the University of Naples was the fact that control was wholly in the hands at first of the Royal Chancellor and then of the Grand Chaplain. Examinations for the doctorate were superintended by him and the diploma or license was issued in the name of the king. Such control retarded progress for some time. Under the reorganization of 1860 the university has made steady advance. The following faculties are maintained: jurisprudence; medicine and surgery; physical science and mathematics; philosophy and letters; and a school of pharmacy. The student enrollment in 1908 was 6602, of whom 2627 were in the faculty of jurisprudence.

NAPOLEON AND EDUCATION. — The educational system which was introduced by Napoleon and which in its outline has survived in France to the present day is of interest as an attempt to realize a dominating political ideal through the schools. Political aims and political ideals could, according to Napoleon, only be realized through a well-organized teaching body. "Of all political problems," he says, "this is perhaps of prime importance. An established political state will be impossible without a teaching body with established principles." And elsewhere: "My aim in establishing a teaching body is to have a means of directing political and moral opinions." The organization of the Jesuits to a large extent could have realized his objects, and he would have put the schools in their charge, if they had not been subservient to a "foreigner." For a time he and his advisers thought of employing the Oratorians, or the Congregations of the Doctrine, or the Benedictines, or all three. Later, however, he was opposed to ecclesiastical teachers, because "priests look upon this world only as a vehicle to conduct to the next. I want the vehicle to be filled with good soldiers for my armies." Good soldiers and citizens loyal to his person were to be product of his educational scheme. The basis of instruction was to be (1) the Catholic religion, (2) loyalty to the emperor, and (3) obedience to the statutes of a teaching body. All alike, pupils and students, teachers and professors, were to be creatures of a large administrative machine. A curious omission from Napoleon's scheme was the neglect of a thorough provision of elementary education.

Elementary schools are mentioned in the decree of 1808, and their organization was promised for the future, but little was done. The Christian Brothers (*q.v.*) were to be allowed to conduct their schools, provided they became members of the university and took an oath of allegiance. In this way Napoleon hoped both to economize on the budget and to break the independence of the Christian Brothers. Napoleon seems to have repented of the omission, but too late, when he issued a decree in 1815 (Apr. 27) "on the importance of primary education for the improvement of the condition of society."

By the Law of May 10, 1806, the Imperial University was created and charged with the sole care of public instruction and education. The decree organizing the university was issued on Mar. 17, 1808, and contained the following features: All public education is in the charge of the university. No school or educational institution could be opened outside the university or without the authority of its head. No one could open a school or teach publicly unless he were a member of the university or a graduate of one of its faculties. The university for administrative purposes was to be divided into academies, each with its own faculty; *lycées*, thirty in all, for instruction in classics, history, rhetoric, logic, and the elements of mathematics and physical science; *collèges*, or municipal secondary schools, giving but the elements of the curriculum of the *lycées* without rhetoric and logic; private institutions of secondary character; boarding schools; and elementary schools to teach reading, writing, and elements of arithmetic. At the head of the whole system was to be a grandmaster assisted by a chancellor, or secretary, and a treasurer; a University Council of thirty members was to be appointed partly by the emperor, partly by the grandmaster. Each academy was to have a council of ten. The grandmaster was to appoint twenty to thirty inspectors-general and rectors of academies. Subordinate officers were to be academy inspectors, professors, principals, regents, teachers, etc. To provide teachers a normal school for 300 students was to be created at Paris. The efficiency of the machine was to be further secured by requiring celibacy from all engaged in schools without the rank of professors. No member of the teaching body could leave the service without permission from the grandmaster. By a decree of Sept. 17, 1808, all institutions which were not provided with a diploma from the grandmaster by Jan. 1, 1809, were to be closed. In 1811 (decree of Nov. 15) the system was further extended by a proposal to raise the number of *lycées* to 100; by compelling institutions and boarding schools in towns where a *lycée* or *collège* already existed to send their pupils to these schools and to limit themselves to repetition of the school work; by limiting the curriculum given by

institutions and boarding schools in towns where a *lycée* or *collège* did not exist. (For the later development of the system see FRANCE, EDUCATION IN.)

The education of girls Napoleon did not consider to be of importance. For girls the destination is marriage and "of all educations the best is that of mothers." He seems, however, to have been at some trouble to prescribe the curriculum for the school at Ecouen, a boarding school for the daughters and sisters of officers of the Legion. "Religion is an important matter in a public institution for girls. . . . Train believers not reasoners," for religion will supply qualities otherwise unattainable by the weaker intelligence of women. The secular subjects were to include ciphering, the vernacular, orthography, geography, and history; a little botany and natural science for the older girls; music and dancing; but the chief attention was to be devoted to the preparation of mothers and home-makers, so that about three quarters of the day was to be given up, to the manual work connected with a home. The scheme seems to have been carried out, but the severity of the discipline and the burden of the practical work seem to have made the school distasteful to many of the pupils.

NARCOLEPSY.—Is an abnormal condition of sleepiness in which the individual has a tendency to go to sleep many times during the day, the sleep lasting from one or two minutes to several hours. The impulse or tendency to go to sleep is so strong as to be almost irresistible. The condition is sometimes produced by physical causes, such as ocular fatigue, anemia, diabetes, uremia, gout, and certain drugs. It is a common symptom in hysterical persons, and is sometimes a psychic equivalent for epileptic convulsions.

Any unusual amount of sleepiness, especially in children, should be looked at with suspicion, and an appropriate medical examination made to determine its cause. If brought about by a state of fatigue, whether from eye-strain or from any other similar cause, due measures may be taken to overcome it, and the child will return immediately to a normal condition. If the narcolepsy be an epileptic or hysterical symptom, the individual must be treated for these diseases, and if it be found in a child, due allowance must be made by the teacher for the diseased condition. The opposite condition is called insomnia. S. I. F.

NARCOTICS.—Concerning the narcotic effect of tobacco upon health, there has been

much discussion. The fact that the stem and leaves of the tobacco plant contain a poisonous substance (nicotine) which in concentrated doses quickly kills small animals, proves nothing regarding the effect of smoking or chewing tobacco; for in both of these ways of using tobacco, the nicotine is exceedingly diluted, as is the poison found in tea and coffee. It seems certain that indigestion, irritation of the respiratory organs, and heart and nervous disturbance may in some people result from the use of tobacco, while others show no apparent effect. All this refers to healthy adult men, for many medical authorities agree that tobacco is *always harmful to growing boys*, and interferes with their physical and mental development. The whole physiological truth about tobacco so far as now known is that: (1) no one needs it except to satisfy an established habit; (2) many adults are injured by it, and no one knows just how much will do harm to a particular person; (3) some adults are apparently not harmed by limited use; (4) it is decidedly injurious to growing boys; (5) those who avoid establishing the habit in youth do not as a rule care to learn later, for there are no physiological reasons why any one should deliberately set out to learn the use of tobacco in any form.

It is now well known to physicians that temperance is needed in the use of tea and coffee no less than with alcoholic drinks. Their effect is due to the presence of a powerful drug (*e.g.* caffeine), which acts on the nervous system. Nervousness, insomnia, headache, and indigestion are common symptoms arising from their excessive use. Many people are injuriously affected by tea and coffee, but others are apparently benefited by a limited use of these beverages. However, they should never be given to young children.

Concerning the effect of various narcotic drugs in common use there is no question as to disastrous effects of such drugs as opium, morphine, cocaine, laudanum, chloroform, chloral hydrate, and various patent or secret preparations, when habitually used.

M. A. B.

See ALCOHOL, PHYSIOLOGICAL AND PSYCHOLOGICAL EFFECTS OF; TEMPERANCE INSTRUCTION.

NARRATION (Rhetorical).—See COMPOSITION.

NARRATIVE METHOD.—In teaching history in the primary and intermediate grades a systematic study of history by topics or movements is avoided. The children lack the motive for the study of historical facts so organized. Hence, in the lower school grades a basis in historical fact is established through a study of (1) the great personages of history, and (2) the dramatic incidents and stories of history. When events are grouped about a per-

NASCENT PERIODS

sonality, we have the "biographical method"; when the selection of historical facts is made upon the basis of their contribution to an interesting story, we have the "narrative method." These methods are merely preliminary to a more systematic historical study and have a value (1) in interesting children in history, (2) in acquainting them with the main personalities and events of the past, and (3) in giving the pupils a basis for interpreting and motivating later study of a more thorough and scientific type. H. S.

See HISTORY, TEACHING OF.

NASCENT PERIODS. — A term borrowed from chemistry to indicate the periods in child development when certain characteristics are in process of formation.

Human development, both physical and mental, is not uniform, but subject to periods of rapid and slow growth. Many attempts have been made to distinguish these stages of development, the results differing according to the points of view. Thus some of the classifications have been built up upon the theories of recapitulation and other similar theories. Others are based upon anthropological and anthropometric investigations, and still others upon the results of psychological observation and experimentation.

Vierordt distinguishes seven stages, based upon measurements of the bodily organs. They are as follows: (1) from birth to eight months; (2) from eight months to seven or eight years; (3) from seven or eight to fourteen years; (4) from fourteen years to twenty-one or twenty-two; (5) early adult; (6) later adult to sixtieth year; (7) old age. Bagley gives three periods of development during the school life of a child. They are as follows: (1) the transition stage, from the age of six to eight; (2) the formative stage, from eight to twelve; (3) the adolescent stage, from twelve to eighteen.

Kirkpatrick enumerates the following stages, based upon a study of changes in social sensitiveness in the various periods; (1) pre-social, up to close of first year; (2) imitative and socializing stage, up to three years of age; (3) individualizing stage, up to six years; (4) pubertal or transitional, up to eighteen; (5) later adolescence, up to twenty-four.

It is evident that all such attempts at classification must vary with the characteristics selected as the basis of the classification. Furthermore, the ages mentioned are only approximations, and cannot be expected to hold generally. The advantage to the educator of knowing the stages of the child's development lies in the fact that changes are most easily accelerated at the natural time of their appearance and may even be impossible at a later or earlier period. It is also probable that normal development in an earlier period

NATIONAL COUNCIL

lays the proper foundation for development in subsequent periods. E. H. C.

NATIONAL COUNCIL — An organization, within the National Education Association (*q.v.*), consisting of 120 members, elected from the active and life members of the association, and for six-year terms. One half of the membership is elected by the Board of Directors of the National Education Association, and the other half by the council itself.

The first proposal for the formation of such a body was made in 1879 in an editorial in the *National Journal of Education* of Boston. The article awakened much interest, and a number of State Teachers' Associations indorsed the idea. The editor was invited to read a paper on the subject before the Department of Superintendence of the N.E.A., at its winter meeting in 1880, and a committee was later appointed to draw up a plan of organization, to be reported to the directors of the N.E.A., at the summer meeting. The plan was approved by the directors and by the association, and the first council was appointed in that year. Since then there have been some changes in the plan and constitution, and a material enlargement of the membership, but the purpose of the organization, as stated in its constitution, has remained with but little

change. The membership was soon enlarged from the original 51 to 60, at which it remained until the Cleveland meeting in 1908, when it was increased to 120.

The National Council was intended to be a small body of the older and more deeply interested members of the association, who should not only meet for the more serious consideration of fundamental educational questions but should also direct investigations and conduct research. The appointment of special committees for this purpose was distinctly authorized in the articles of organization. The council was also to recommend educational questions or the results of investigation to the directors of the National Education Association for their consideration, and was to make a report to the association on the work of the council for the year. The recording and reporting of current educational progress was to be a part of its work. During the first twenty years of its existence the council rendered valuable service, and the record of its discussions shows that the members considered most of the important topics of the day. Many short but important individual reports were made by members and considered. The *Report of the Committee of Twelve on Rural Schools*, submitted in 1897, and the *Report of the Committee on the Relations of Public Libraries to Public Schools* made in 1899, were longer coöperative studies. During the past ten years, however, the council has considered few problems of fundamental importance.

This plan for a Council of Education has been copied in more or less detail by a number of State Teachers' Associations, and in a few associations such a body is still rendering important service. The difficulty which confronts such a selected body is that, under the democratic methods of election which prevail, and with election open to all members, persons are elected to the councils because of other considerations than ability and willingness to work, the membership is enlarged to make place for others, and the council loses its early vigor and usefulness.

E. P. C.

NATIONAL EDUCATION.—The different aspects of this problem will be found distributed under various topics; *e.g.* ENGLAND; EDUCATION IN; FRANCE, EDUCATION IN; GERMANY, EDUCATION IN; SCOTLAND, EDUCATION IN; and other national systems, where the development of public education is given under the historical sections. For this country see under COLONIAL PERIOD IN AMERICAN EDUCATION; MASSACHUSETTS, STATE OF; and the historical sections of the articles on the other state systems, *e.g.* ALABAMA, STATE OF. See also DEMOCRACY AND EDUCATION; CITIZENSHIP AND EDUCATION; FAMILY EDUCATION; SCHOOL AND LIFE; COURSE OF STUDY, THEORY OF; COURSES OF STUDY, etc., and the articles on the more recent developments in special fields of AGRICULTURAL EDUCA-

TION; COMMERCIAL EDUCATION; INDUSTRIAL EDUCATION. See further ATTENDANCE, COMPULSORY; CHILD LABOR; CHILDHOOD, LEGISLATION FOR THE CONSERVATION AND PROTECTION OF, etc. The general development of the principle of public education is treated under FREE SCHOOLS; see also in this connection FEES; the general method of support is outlined under TAXATION.

NATIONAL EDUCATION ASSOCIATION.—See TEACHERS' VOLUNTARY ASSOCIATIONS.

NATIONAL GOVERNMENT OF THE UNITED STATES AND EDUCATION.

The whole policy of national aid has been a slow and a gradual development, but following a slowly evolving plan. The organization and control of the educational systems themselves have been left to the states, the national government merely aiding and encouraging the states by granting them educational endowments from the vast national domain. As a total the aid granted has been large, but it has been unevenly distributed.

The large national domain was acquired as the result of state cessions, purchase, treaty, and the fortunes of war. The cessions west of the Allegheny Mountains and east of the Mississippi River, made by the original states between 1780 and 1802, formed the beginning of the national domain. This was added to by the Louisiana Purchase of 1802, the Oregon boundary treaty settlement of 1846, and the outcome of the war with Mexico, in 1848. After the consideration of a number of proposals, the Continental Congress, in 1785, adopted a system of rectangular land survey for the new domain, based in large part on the old New England system of "town planting," which, after slight modifications, was adopted in final form in 1796, and is known as the Congressional land survey. Under it the national domain has been laid out into rectangular townships, six miles square, and these have in turn been divided into sections, one mile square. From this form of survey the lands have been sold and the endowment grants made.

Land Grants for Common Schools.—*Disposal of the Lands.*—In April, 1783, Colonel Timothy Pickering drew up certain propositions for settling a new state in the national domain, in what is now Ohio, the same to be settled by officers and soldiers of the federal army. The proposal of Pickering is significant as containing the earliest suggestion of national land grants for education, as follows:—

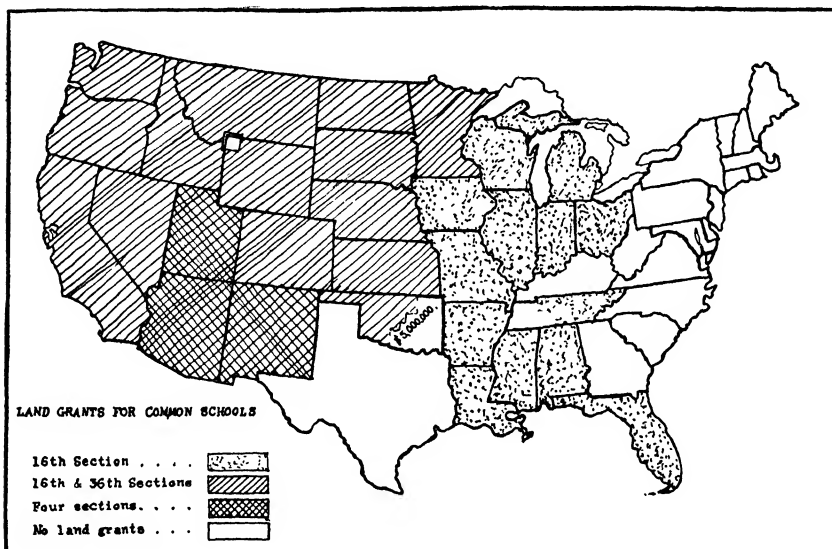

"Art. 7. These rights being secured, all the surplus lands shall be the common property of the State, and be disposed of for the common good; as for laying out roads, building bridges, erecting public buildings, establishing schools and academies, defraying the expenses of government, and other public uses."

Two years later the Ordinance of 1785, ordering the rectangular system of survey, contained a provision that "there shall be reserved the lot No. 16 of every township for the maintenance of public schools within the said township." The famous Ordinance of 1787 merely stated in principle, for the entire Northwest Territory, what had been specifically provided for in a part of Ohio in 1785.

In 1787 a New England company, known as "The Ohio Company of Associates," purchased 1,500,000 acres of land on the Ohio, and in arranging for this sale Congress agreed with the purchasers to reserve Section 16 in every township for schools, and Section 29 for religion; and to grant, in addition, two complete townships for the benefit of a university. The

make additional concessions. The new Congress also refused to grant lands to the Ohio Company in lieu of those of Section 29 (religion) which were found to have been sold, and the grant of sections for religion nowhere appears again. In 1792 the new state of Kentucky and in 1796 Tennessee were admitted to the Union, but no land grants were made to them.

Ohio establishes a Type and a Policy.— With the admission of Ohio, in 1802, our land-grant policy for education really begins. A definite precedent was here established, which has been followed, and extended, in the admission of all subsequent states. The enabling act for the admission of Ohio contained a definitely proposed bargain, which, if accepted by the state, was to be binding on Congress,

university lands were given to the care and management of the legislature of the future state, but the control of the sections for schools and religion was left undecided. Similar terms were made in the contract for the sale of 1,000,000 acres on the lower Ohio to John C. Symmes in 1788. In these laws and grants by the Congress of the Confederation may be seen the beginnings of a national land-grant policy, though it was some years afterward before a settled policy may be said to have been determined upon. On the organization of the National Government in 1789, many petitions were presented to the new Congress for special grants of land and for the sale of land at reduced prices, and it is greatly to the credit of the Congress that it consistently refused to

and irrevocable. If the new state would agree by ordinance to exempt from taxation all public lands sold by Congress within the state, for five years after sale, Congress agreed to give to the new state certain salt springs; to give to the state 5 per cent of the net proceeds of the sale of all public lands within the state; and to give the 16th section for schools to the inhabitants of each township. This was a definite exchange of property and rights of value, and Congress was actuated as much by a desire to increase the market for national lands as it was to aid in the establishment of schools. Nevertheless, this bargain inaugurated a policy which was followed in the admission of subsequent states, even after the taxation exemption provision was dropped.

In 1803 Congress confirmed to Ohio all preceding grants for schools; extended the grants to certain reservations not before included; granted the state another township for a university; declared the grants "to be for schools, and for no other use, intent, or purpose whatever"; and vested the control of the school lands in the legislature, in trust for the purposes mentioned. The same year the provisions of the Ohio act were extended to the territory "south of the state of Tennessee," and in 1806 Congress, in settling a dispute with Tennessee, provided for the reservation of "640 acres to every 6 miles square" for schools, and granted the state, in return for certain concessions, 100,000 acres for academics and a like amount for two colleges. With the admission of Indiana in 1816, Mississippi in 1817, Illinois in 1818, and Alabama in 1819, bargains and grants similar to the one for Ohio were made by Congress. With the admission of Missouri in 1821 the grants for schools were extended to the Louisiana Purchase, as well as to the national domain derived from the state cessions. Louisiana had received no grant of school lands on its admission in 1812, but in 1834 the 16th section was granted the state, "wherever the same had not been sold." All states thereafter admitted received grants of lands for schools, with the exception of Maine, which was carved from Massachusetts; Texas, in which the national government owned no land; and West Virginia, which was carved from Virginia.

Three Types of Grants; Leases.—Three types of grants were used before 1840. In the Ohio type of grant the 16th section, or its proceeds, was "granted to the inhabitants of each township, for the use of schools." Indiana in 1816 and Mississippi in 1817 followed the Ohio type of grant. With the admission of Illinois in 1818, the 16th section was "granted to the state, for the use of the inhabitants of such township, for the use of schools." Alabama in 1819 reverted to the Ohio type of grant, but Missouri in 1821, and Arkansas in 1836 followed the Illinois type of grant. By the time Michigan came to be admitted in 1837, the evils of both forms of grants had become so apparent that the convention which framed the constitution memorialized Congress to grant the 16th section lands "to the state, for the use of schools," and to be applied without reference to township lines. To this Congress assented, and this wise form of grant has been followed in the case of all subsequent states. By about 1850 the policy of making grants for schools had become settled, and after that time the reservations were ordered at the time the survey of the territory was made, the sections being held in reserve for the future state.

At first there was no permission to sell the school lands, and they were held under lease. This proved unprofitable, and in 1824 Ohio

led the way by memorializing Congress for permission to sell her school lands. This was granted in 1826, and similar permission was soon granted to the other states. This led to much waste and many abuses. Beginning with Colorado in 1876, Congress has imposed increasing restrictions as to the sale price, so as to insure proper returns.

Additional Section Grants.—Up to 1850 all states admitted, beginning with Ohio, had received the 16th section for schools, except Maine and Texas. When the survey of the Oregon country was ordered in 1848, Congress departed from the previous policy and ordered the reservation of sections 16 and 36 in every township for the benefit of schools in the future state or states. California, entering the Union in 1850, was the first state to receive two sections, and two sections were granted to all new states thereafter, except West Virginia, up to 1896. When Utah was admitted in 1896, four sections in each township, the 2d, 16th, 32d, and 36th, were granted to the state for schools, and this form of grant was also followed in the admission of Arizona and New Mexico. In admitting Oklahoma in 1907 the most liberal of all grants was made. The state was granted the 16th and 36th sections for schools; the sum of \$5,000,000 in money, in lieu of grants in Indian Territory lands; section 13 for normal schools, the agricultural college, and the university; section 33 for charitable, penal, and reformatory institutions; and other acreage grants for individual institutions mentioned further on in this article.

Value of these Grants.—The total of these land grants for common schools is about 81,064,300 acres. This is equal to an area about the size of the states of Ohio, Indiana, and Illinois combined, and, at the traditional price of \$1.25 per acre for government land, would be worth about \$100,000,000. As a matter of fact, the grants have produced much more than this amount, the sale price of lands in the newer Western states being many times the old figure. Many of the earlier grants were grossly mismanaged, and in some cases the money when accumulated was borrowed by the state and spent, leaving to-day only "a perpetual obligation" on which the state pays interest from the proceeds of general taxation. In the states admitted since 1850, however, the land grants have been looked after with greater care, and since 1875 excellent results have been obtained. The accompanying map shows the distribution of the grants, and the following tabulated summary shows the approximate values of them. That a total permanent school fund of \$500,000,000 may in time be obtained from these school-section grants seems probable, while the amount may eventually prove still larger. Of this estimate of \$500,000,000 but \$6,000,000 is in the old slave states; \$35,000,000 is in Oklahoma; \$27,000,000 is in the old

Northwest Territory states, two fifths of which is land belonging to the city of Chicago; \$157,000,000 is in the Plains states; \$205,000,000 in the so-called Mountain states; and \$72,000,000 is in the three Pacific Coast states.

GROUPS OF STATES	ACRES RECEIVED IN SECTION GRANTS	FUND DERIVED FROM SALE (APPROXIMATE)	VALUE OF UNSOLD LANDS (APPROXIMATE)
11 states adm. before 1825	6,465,382	\$15,250,000 ¹	\$13,000,000
6 states adm. 1825-1849	4,726,153	8,750,000	1,250,000
8 states adm. 1850-1889	20,223,353	35,500,000	95,750,000
10 states adm. 1889-1912	43,649,412	43,500,000	300,000,000
TOTALS	81,064,300	\$103,000,000	\$410,000,000

¹ Three fourths of this amount is land belonging to the city of Chicago.

Protests of the Older States. — It will be noticed from the map of the United States, showing the distribution of these land grants for common schools, that certain states received no grants for schools whatever. This has for long been a source of dissatisfaction and protest on the part of the older states. Maryland in 1821 drew up a long and detailed statement, which it transmitted to Congress and to each of the states, setting forth the facts as to the grants; declaring that each state in the Union had "an equal right to participate in the benefit of the public lands, the common property of the Union"; and requesting Congress to make similar appropriations of land to each of the other states. The legislatures of Maine, Vermont, New Hampshire, Connecticut, Rhode Island, New Jersey, Delaware, and Kentucky indorsed the Maryland memorial and also transmitted to Congress carefully prepared memorials praying for similar grants for common schools. Ohio alone among the states opposed the grants. The Committee on Public Lands of the Senate was "instructed to inquire into the justice and expediency" of making such grants, and reported adversely, holding that the so-called grants had in reality been "sales bottomed on valuable considerations," and that to grant large areas of land to other states would greatly impede the development of the states in which the land was located. On the other hand, the committee stated that it would be both "just and expedient to grant a per centum on the sales of public lands for the purpose of promoting education in such states as had not received the aid of the government." This was not done.

The question has come up from time to time, but no settlement has ever been reached. One of the most recent proposals was a bill introduced into Congress in 1894-1895, proposing to give sufficient land to the states to equalize all grants to an equivalence of two sections for all. It was estimated that this would require about 28,000,000 acres, but no action was taken. It can hardly be denied that the older

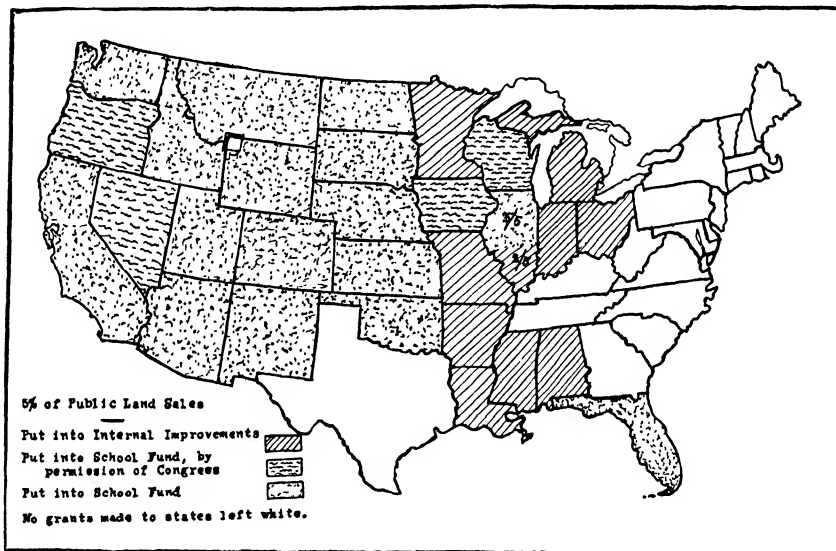

states have not received their just share in these grants from the national domain. That they would have wasted their share had they been given section grants at the beginning, seems probable. The story of the waste of the school lands by the states admitted before 1850, and the squandering of the Surplus Revenue distribution of 1837 by most of the older states, leaves little doubt as to what would have been the result. That these grants have greatly stimulated an interest in education in the newer states to the west cannot be questioned, and it is probable that national grants to the older states, even now, might awaken a new interest in the work of public education.

Other Grants for Common Schools. — *Saline Grants.* — In the bargain made at the time of the admission of Ohio, certain saline lands were given to the state, and these were in turn put into the school fund; 24,216 acres were granted in all, and their final sale added \$41,024 to the school fund. Indiana, similarly, received 23,830 acres, from which about \$85,000 were derived. Shortly afterward it became customary to grant two full townships of saline lands to each state, on its admission, to be devoted to any purpose the state saw fit, though in the admission of all states after Colorado (1876), except Utah, the grant of saline lands has been omitted. In Utah all saline lands in the state were given to the state for the benefit of the state university. About 900,000 acres of saline lands have been granted to the different states, most of which have been used for educational purposes. Some states have added the proceeds to the permanent school fund, some have used the lands to endow the normal schools, and one or two states have added the lands to the university grants. Just how much these saline grants have produced is not known, but probably something over a million dollars.

The Five Per Cent Fund. — In the enabling act for the admission of Ohio the plan of granting 5 per cent of the net proceeds of the sale of all public lands lying within the state, for internal improvements, was begun, and has since been continued in the case of all new states, except Maine, Texas, and West Virginia. With the admission of Illinois in 1818, a portion (three fifths) of this fund was for the first time given for education, and was used for the normal university. This state, however, formed an exception, as the fund was not again devoted to education for nearly thirty years. Since 1860 the grant has been uniformly given for additions to the common school fund of the states, and, in the case of all states admitted between 1845 and 1860 except Minnesota, the fund has since been diverted to education, with the permission of Congress. In all \$7,187,316 had been added to the permanent school funds of the different new states from this source, up to 1910, and four fifths of this has been to the school funds of states west of the Mississippi River.

The Surplus Revenue. — The idea of devoting a portion of the money derived from the sale of public lands to the cause of education, and of dividing it in some equal proportion among the states, seems to have been often considered. In 1826 the Committee on Public Lands of the House presented a report declaring that the public domain constituted "a common fund for the joint benefit of the states," and recommended a distribution among the states of a portion of the proceeds of land sales for the support of common schools. Between 1817 and 1827 there was an annual surplus of national revenue of from two to six million dollars. By 1827 the extinction of the national debt seemed certain, and, as it was at that time believed that the money could not be spent,

a presidential veto, it was put in the form of "a deposit of money among the states." After reserving \$5,000,000, all money remaining in the Treasury on Jan. 1, 1837, was to be deposited with the states, in proportion to their representation in Congress, and in four equal quarterly installments. Only three payments were ever made, as the panic of 1837 soon left the Treasury empty. Altogether, \$28,171,453.86 was "deposited," the deposit varying from \$286,751.49 to Delaware, to \$4,041,520.71 to New York. The deposit was everywhere regarded as a distribution, and none of the money has ever been called for. Of the total amount distributed, approximately \$7,500,000 actually exists to-day, the interest on all of which is devoted to schools. Over

constitutionally, for internal improvements, visions of a great annual surplus began to appear. As early as 1826 a bill to distribute \$5,000,000 among the states was proposed. The bill failed to pass, but the idea was cherished. In 1831 the legislature of Pennsylvania asked Congress for a distribution. In 1833 Clay's bill for the distribution of the land revenues among the states was passed, but vetoed by President Jackson. The money was to be used for education, internal improvement, colonization, or the extinction of state debts. The matter soon became a political issue, and a feeling of injustice on the part of the old states ran through it all. Finally, in 1836, the distribution so long talked about was made; though, to avoid

half of this amount is that of New York. There is also an interest charge, in eight states, on \$6,405,837.74 of lost funds, raised by taxation and now devoted to the support of schools. The school funds of the different states actually received about one fourth of this distribution, and to-day draw interest on about half of it. Almost all of the deposit not put into school funds was squandered or lost.

The Internal Improvement Act of 1841. — One section of this law (8) has been of much importance to education. By its terms, 500,000 acres of public land were granted to each state admitted after 1800, except Maine, to be selected by the state, and the same grant was made to all new states admitted thereafter up to 1889, except Texas and West Virginia.

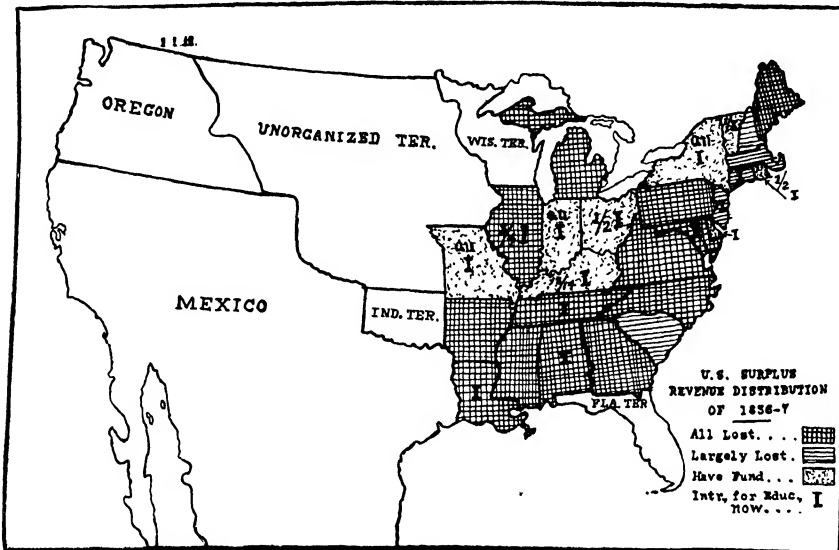

NATIONAL GOVERNMENT

The land was at first given for internal improvements, but after 1845 the grant was diverted to education in all cases except Minnesota. Beginning with the states admitted in 1889 and after, Congress has made important specific grants, ranging from 500,000 to 2,160,000 acres, to each new state in lieu of this and the salt land grants. A brief statement of the amount and approximate value of these 500,000 acre grants to new states, made

NATIONAL GOVERNMENT

the sales have averaged two to five times this amount. In Arizona and New Mexico certain lands cannot be sold for less than \$25 an acre. The total of all the specific grants to the last ten states admitted is 11,243,080 acres. Of this amount 6,656,540 acres have been for purposes specified above as educational. The educational lands granted to the last ten states are worth from \$40,000,000 to \$60,000,000, at least.

Swamp Land Grants.—In 1849 Congress granted to the state of Louisiana, on its appli-

under the provisions of the law of 1841, is as follows:—

- General grants made to the states admitted before 1889. Put into the common school funds of the states, 5,000,000 acres. Minimum sale price fixed by law, \$1.25 per acre. Lands sold so far (about 1) have produced about . . . \$6,000,000
 Lands still on hand, probably worth about . . . \$8,000,000
 Total gains to common school funds from grants up to 1889, about . . . \$14,000,000.
- Specific grants for educational purposes, 1889 and since, in lieu of the 500,000 acre grant for schools:—For universities, 1,040,000 acres; for schools of mines, 680,000 acres, for agricultural colleges, 1,000,000 acres; for normal schools, 1,260,000 acres; for schools for the deaf, dumb, and blind, 590,000 acres; for reform schools, specifically, 230,000 acres; for reformatory, penal, and charitable institutions, 1,180,000 acres, and in Oklahoma Section 13 (706,540 acres) was granted, $\frac{1}{4}$ for normal schools, $\frac{1}{4}$ for the university, and $\frac{1}{4}$ for the agricultural college. Other specific grants have been for such purposes as insane asylums, public buildings, penitentiaries, hospitals, and irrigation. On most of this land a minimum sale price of \$10 an acre was placed, and in most of the states

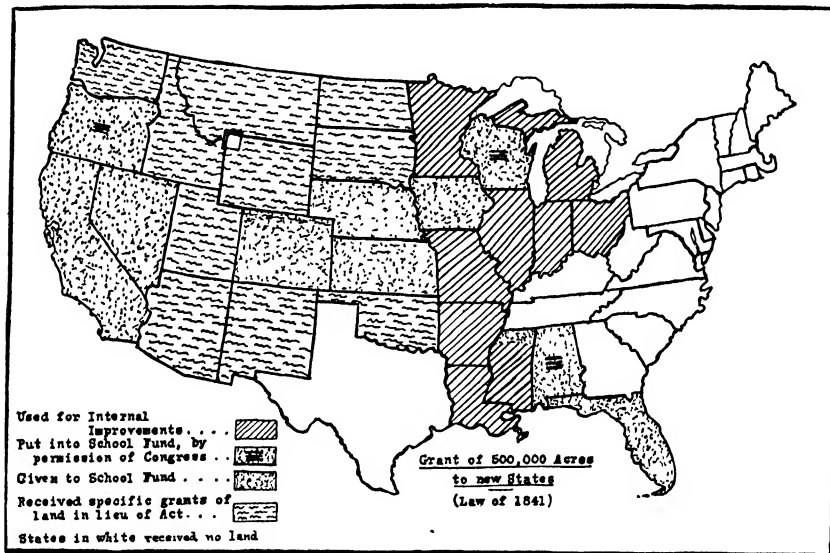

education, all of the swamp and overflowed lands within the state, the proceeds to be used in constructing levees and drains. The following year the law was made general, and many states have shared. The act applied only to the new or public-land states. In 1857 all lands so far selected were confirmed to the states. In 1860 Minnesota and Oregon were granted swamp lands, and in 1866 California received such grants. Since that date the grant has not been made to any new state. A number of the states have used this grant, or the balance after paying for drainage work, for education instead of for internal improvements, and have put either all, or the net proceeds, into the permanent state school fund. Illinois, for example, has received much of its permanent school fund from this source, if we omit the lands in the city of Chicago. A total of something over 60,000,000 acres of swamp lands was granted to the states, about three fourths of which grants were devoted to educational purposes, and mostly put into the common school funds. These have probably

brought in from \$12,000,000 to \$15,000,000 for educational purposes. Perhaps two thirds of this amount is in existence to-day, some of it having been spent by the states, and an interest charge being all that is left. Some swamp lands are still unsold.

Forest Reserve Income. — By an act of Congress in 1908, Congress now makes grants of 25 per cent of the income of each national forest reserve, for the benefit of schools and roads within the county in which the forest reserve is located. This grant produced \$438,702 in 1909-1910, and in time will produce very substantial incomes for certain counties having national forest reserves within their borders.

grant was changed in purpose, on the request of a number of the states. Such of the saline-land grants and the deposit fund as went to education was so devoted by the states.

Between 1867, when Nebraska entered the Union, and 1889, but one state (Colorado, 1876) was admitted. When Congress came to admit the two Dakotas, Montana, and Washington in 1889, and Wyoming and Idaho in 1890, the national aid policy, as it had finally evolved, is seen. The two sections in each township in the state (Indian reservations excepted) were granted to the state for common schools; the 5 per cent fund was also granted to be devoted to the same purpose; and, in lieu of the swamp land grants and the 500,000 acre grant,

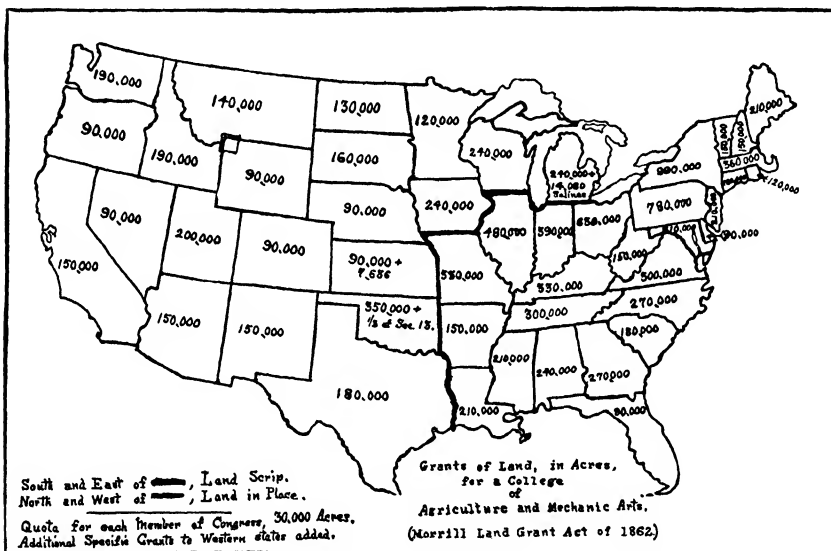

The National Aid Policy as Finally Evolved. — Starting from a form of bargain for the sale of land, the policy of making grants for educational purposes has gradually evolved into one of very marked proportions. Perhaps the pressure of the new states for grants for educational purposes has done more to bring these educational grants about than has the desire of Congress to help education in the states. The 16th and succeeding section grants were given for schools from the first, but the form of grant was finally evolved under a request from a state. The 5 per cent fund was at first given for internal improvements, but was gradually diverted to education. The swamp land grants have been devoted to educational purposes by the states without suggestion from Congress. The 500,000 acre

500,000 acres of land, to be located by the state, were granted for specific educational objects, such as the university, the agricultural college, normal schools, a school of mines, reform schools, deaf and blind asylums, and charitable and reformatory institutions. A minimum sale price of \$10 per acre was fixed, freedom from sectarian or denominational control for all schools was required to be pledged by the state, and the state was required to pledge the inviolability of all the educational grants. These grants reached a climax in the enabling act for Oklahoma in 1907, and attained a scale of munificence equaled nowhere else. (See special articles on OKLAHOMA, STATE OF, for a detailed statement of these grants; on the other state school systems, for a statement of their grants, and the

amount of their permanent school funds; and on New Mexico, STATE OF, for a statement of the grants made to Arizona and New Mexico.) The grants to Oklahoma totaled 3,876,163 acres, estimated as worth \$20 per acre as a minimum. This is an area three fourths as large as the state of Massachusetts.

One new feature of all the recent (since 1889) enabling acts is the grants of land for normal schools, asylums for the care of defectives, and charitable and penal institutions. A few states, still earlier, devoted certain of their land grants to the endowing of normal schools, but it is only since 1889 that direct grants for these schools have been made by the National Government. In all, something over a million and a half acres of land have been

poses of seminaries of learning, were confirmed to the state. In 1806 Tennessee was granted 100,000 acres of land for two colleges, and a similar amount for county academics. The enabling act for Indiana in 1816 granted the state two townships "for a seminary of learning," and vested their control in the legislature of the state. The enabling acts for nearly all of the public land states admitted since have contained similar grants, and, when omitted from the enabling acts, equivalent grants have been made at some other time. All states have received two townships (72 sections; 46,080 acres), and a few have received a larger amount. Beginning with the states admitted in 1889, Congress has, in each case except Wyoming, made specific grants in addition to

used to form endowment funds for normal schools. This is equal to an area of about one third the size of the state of New Jersey. Of this, 95 per cent has been in the ten states admitted since 1889, only two of which are east of the Mississippi River. Each of these new states should derive a fund from the grants of at least \$1,000,000 for the endowment of its normal schools, while Oklahoma should exceed twice that sum.

Aid to Higher Education. — *Seminary Township Grants.* — The ordinance, passed in 1787, for the sale of 1,500,000 acres of land to "the Ohio Company of Associates," made the first grant of two townships for a university. On the admission of Ohio as a state in 1802, the three townships, previously granted for pur-

the state university, and often also for a school of mines as well. In the case of Oklahoma one section of land was granted in each township (Section 13) for the further endowment of the university and the state preparatory school (one third), the agricultural college (one third), and the normal schools (one third). A total of about three and a half millions of acres of land has been granted to the states for university purposes, not including the grants for colleges of agricultural and mechanic arts, to be mentioned further on. This is equal to an area of about two thirds the size of the state of Massachusetts. These grants have produced actual funds of about \$5,000,000, and unsold lands have an approximate value of \$25,000,000 to \$30,000,000, and may produce much more. Nearly all of

the unsold land is in states to the west of the Mississippi River.

The accompanying map shows the distribution of these grants. The old states, it will be noticed, have never shared in these grants. From time to time proposals to make grants of land to the old states as well have been up for consideration. In 1819 the Committee on Public Lands of the House was instructed "to inquire into the expediency of appropriating 100,000 acres of land to each state, for the endowment of a university in each state." They reported against the plan, largely because of the disturbance in land prices which would be produced and the conflicts which would arise between states from the location of the grants. If such aid were to be granted the committee was of the opinion that "it should be given in money." These are the same objections which were urged against the Maryland proposal in 1821, and against all other similar proposals up to 1862.

The Land Grant Colleges.—In 1850 Michigan petitioned Congress for a grant of 350,000 acres of public land to aid the state to endow a college for the teaching of agriculture, but the grant was refused. In 1858 Michigan renewed the petition, and in 1859 a bill making such a grant finally passed both houses of Congress. The bill granted to each state 20,000 acres of public land for each senator and representative in Congress, to which the state would be entitled by the census of 1860, to be used in founding a college for instruction in agriculture and mechanic arts. The bill was opposed by the Southern members, and was vetoed by President Buchanan, in a message which is an interesting summary of the old objections to such grants. In 1862 a bill drawn on similar lines, except that the grant was raised to 30,000 acres for each member in Congress, and instruction in military science and tactics was added, was passed and signed by President Lincoln. This was the famous Morrill Land Act. By subsequent legislation the time for accepting the grant was extended to 1869, and the time for opening the colleges to 1874. States yet to be admitted, and states which had been in rebellion, were specifically included in the grants. In all, including additions made by recent enabling acts, a total of 11,367,832 acres has been granted for colleges of agriculture and mechanic arts as a result of the new policy inaugurated in 1862. This is an area half as large as the state of Indiana. The map shows the distribution of the grants, and it will be seen that for the first time the old states received a share. Eighteen states added the endowment to that of their state universities, and combined the two institutions into one. Four states gave the grant to private colleges or universities already established within the state. The remaining states founded separate higher institutions of learning. (See special article on AGRICULTURAL EDUCATION.)

The financial returns from this large grant of land for higher education have been very disappointing, although the educational returns have been large. A compilation from the most recent returns (1910) gives the following as the results of the grant:—

Total acres granted, law of 1862, and subsequent grants	11,367,832
Total acres sold to date	9,570,401
Total funds produced from these lands sold	\$13,736,178
Total annual income from these lands, for all colleges	\$823,400
Acres of land still unsold, mostly western	1,797,431
Estimated value of these unsold lands . .	\$15,020,300
If sold for estimated value, total funds would be	\$28,756,478

This total is distributed as follows:—

The 28 states to which land scrip was issued, received	7,940,000 acres
These states still have unsold	47,600 acres
The fund produced in these states is . .	\$6,504,507
Average sale price per acre	\$0.83
The 20 states to which lands in place were granted, received	3,653,200 acres
These states still have unsold	1,797,431 acres
The lands sold have produced a fund of . .	\$7,171,671
Average sale price per acre	\$3.99
Estimated value, at minimum sale price, of lands remaining unsold	\$15,020,300
Probable sale value, between	\$25,000,000
and	\$35,000,000

It is in the ten states admitted from 1889 on that the large funds in the future are to be expected. Of the 9,500,000 acres granted before 1870, 8,050,000 acres, or 84 per cent, were in land scrip. The result was that all of the states were trying to sell land at the same time, the market was glutted, the price of land dropped to as low as thirty-five cents an acre, and much of it was sold for fifty cents to sixty cents an acre. The low average sale price per acre shows the result.

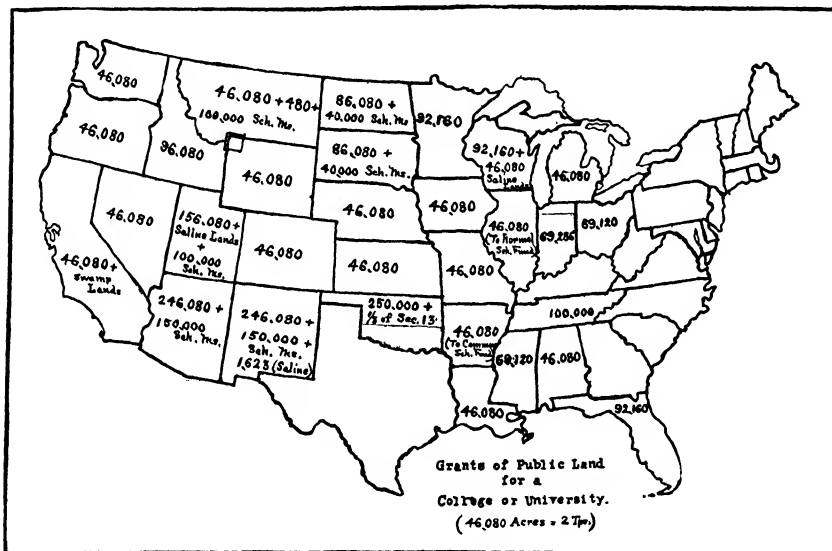

The results of these grants, educationally, have been quite different. Probably no aid given by the National Government for education has ever proved so fruitful as have these grants for colleges of agriculture and mechanic arts. Instead of causing the states to lean upon the National Government for the support of their educational systems, as feared by President Buchanan, the result has been the opposite. New and vigorous colleges have been created; small and feeble state institutions have been awakened into new life; the agricultural and engineering professions have been developed; and the states have been stimulated to make large and rapidly increasing appropriations to these colleges and to their state universities.

National Money Grants.—In 1887 additional grants were made to these land-grant colleges, and a new departure in the matter of government aid was made. A direct appropriation of \$15,000 per year, "from the proceeds of the sale of public lands," was made from the National Treasury to each state for the maintenance of an agricultural experimental

station, to conduct "researches or experiments bearing directly upon the agricultural industry of the United States." What was for so long regarded as wholly unconstitutional was now accomplished in fact. In 1905 the amount was increased to \$20,000, and thereafter to increase by \$2000 a year for five years, or until a maximum of \$30,000 was reached (which would be in 1910-1911), after which the annual sum should be \$30,000. Up to June 30, 1912, a total of approximately \$14,424,000 has been paid directly to the states from the National Treasury for experimental work in agriculture. These payments have been so carefully safeguarded that there has been no misappropriation of funds, and the government makes no payments to the states except upon the pro-

The College of Agriculture in the Territory of Hawaii and the new University of Porto Rico have been admitted to share in these grants, making a total of fifty states and territories eligible, by 1912, for total grants of \$80,000 a year, or a total annual cash appropriation to the agricultural colleges of \$4,000,000. Up to June 30, 1912, the total cash grants under this latter appropriation have amounted to \$23,920,000, and under both forms of grant to approximately \$38,000,000.

Certainly no grants which the National Government has made to the states for educational purposes have been so well administered as the agricultural grants, and probably no grants have given so large a return in the advancement of scientific knowledge or the

duction of evidence that actual expenditures, for the purposes set forth in the act, have been made.

The results under this grant proved so beneficial that in 1890 what has often been called "the second Morrill Act" was passed. This act provided for a direct annual grant to each state, for maintenance and for the further support of the agricultural colleges. The grant began with \$15,000 a year to each state, and was to increase by \$1000 a year for ten years, or until an annual grant of \$25,000 was reached. In 1907 Congress further extended it, and provided that the annual grant, then \$25,000, should increase by \$5000 per year, until a maximum grant of \$50,000 to each state was reached. This will be in 1911-1912.

general welfare of the nation. This has been in part due to better restrictions imposed by the National Government in making the grants, and in part to the fact that the grants have been handled by the colleges themselves, and not by the legislatures of the states.

Proposals for Additional Grants for Public Schools. — The excellent results obtained from the grants to the agricultural colleges have, within recent years, inspired a number of proposals to extend such money grants to other forms of public education. The "Davis Bills," which have been before Congress in recent years, have proposed to grant national aid "for agricultural and industrial instruction in secondary schools, for normal instruction in agricultural and industrial subjects in normal

NATIONAL GOVERNMENT

schools, and for branch agricultural experimental stations." So far none of these bills have succeeded in passing Congress, owing to opposition to the endowment of one class of high schools to the exclusion of other kinds of such schools.

Total of National Grants for Education.—While education has received but an insignifi-

NATIONAL INSTITUTIONS

cant fraction of the money appropriated for all purposes by the National Government, the total amount, spread over more than a century of our national life, has in itself been rather large. Briefly summarized, it has been about as follows, though in a number of cases the figures given are not exactly accurate, but rather the nearest possible approximations.

GRANT AND PURPOSE	ACRES GRANTED	FUND DERIVED FROM SALES	PROBABLE FUTURE INCOME ¹	TOTAL INCOME
1. <i>For Common Schools:</i>				
Sections for Schools	81,064,300	\$103,000,000	\$410,000,000	\$513,000,000
Saline Grants	c. 900,000	c. 1,000,000	c. 1,000,000	1,000,000
Five Per Cent of Land Sales		c. 7,187,316	c. 7,000,000	14,000,000
Surplus Revenues		c. 14,000,000	c. 14,000,000	14,000,000
Internal Imp. Act	5,000,000	c. 6,000,000	c. 8,000,000	14,000,000
Swamp Land Grants	c. 45,000,000	c. 15,000,000	c. 2,000,000	17,000,000
Forest Reserve Per Cent		c. 1,000,000	c. 25,000,000 ¹	26,000,000
Totals	c. 131,964,300	c. \$147,187,316	c. \$452,000,000	\$599,000,000

University Grants	3,407,643	c. 5,000,000	c. 27,500,000	32,500,000
Land Grant Colleges—				
Grants of Land	11,367,832	13,736,178	c. 25,000,000	39,000,000
Exp. Station Grants		c. 14,000,000	30,000,000 ¹	44,000,000
Laws 1890 and 1907		23,920,000	62,500,000 ¹	86,420,000
Totals	14,775,475	c. \$56,656,178	c. \$145,000,000	\$200,920,000
3. <i>Grants for Other Types of Schools</i>				
Normal Schools	c. 1,500,000	c. 2,500,000	c. 17,500,000	20,000,000
Deaf, Dumb, and Blind	560,000		5,600,000	5,600,000
Reform Schools	c. 500,000		5,500,000	5,000,000
Totals	2,560,000	c. \$2,500,000	c. \$28,100,000	\$30,600,000
4. <i>Summary of Grants</i>	c. 149,299,775	206,343,494	725,100,000	829,520,000

¹ Calculated for twenty years into the future, at present rate of increase.

The land grant policy was begun in the days when land was about all that the National Government had to give; the money grants represent a much later development.

See also the article on NATIONAL TEACHING INSTITUTIONS, and the types of schools and institutions referred to in the text, especially AGRICULTURAL EDUCATION; TECHNICAL EDUCATION, etc.; the article on STATE VS. NATIONAL EDUCATION deals with the development of state education; see further articles on the individual state systems, *e.g.* ALABAMA; ARKANSAS, etc. For the relations between governments and education in foreign countries see the articles on the national systems, *e.g.* ENGLAND, EDUCATION IN; FRANCE, EDUCATION IN; GERMANY, EDUCATION IN.

NATIONAL TEACHING INSTITUTIONS OF THE UNITED STATES GOVERNMENT.—In addition to aiding education in the various states (see special article on NATIONAL GOVERNMENT AND EDUCATION), the National Government maintains a number of teaching and other institutions of an educational nature, and has rendered assistance in the establishment of education in the territories apart from the mainland. These may be mentioned briefly here, and reference made

to other articles in which a more detailed statement is made on the different institutions.

In the District of Columbia.—The free public library of the city of Washington, the free public schools of the District of Columbia (*q.v.*), the National Training School for Boys, the Reform School for Girls, and the Industrial Home Schools for both races are teaching institutions maintained within the District of Columbia. Appropriations are also made for the instruction of the deaf, dumb, and blind within the District. The expenses of all of these institutions are met, half by the National Government, and half by the District of Columbia. Under the Department of the Interior, the Columbian Institute for the Deaf and Dumb, and Howard University (*q.v.*), an institution for the colored race, are also maintained by the National Government in the District of Columbia. The Library of Congress (see CONGRESSIONAL LIBRARY), in the city of Washington, is another educational institution maintained by the National Government, the appropriation for its maintenance in 1910 being \$841,755.18.

War and Navy Departments.—The United States Military Academy (*q.v.*), at West Point, New York State, founded in 1802, is a national college for the training of engineers and officers for the army. The appropriation

NATIONAL INSTITUTIONS

for maintenance in 1910 was \$807,646 06. The Army War College at Washington, the Army Service Schools at forts Leavenworth and Riley, the Army Engineers' School at Washington, and various officers' schools at military posts are all forms of education for the army maintained by the National Government. The total appropriation for all of these institutions, including new buildings, was \$2,234,598 in 1910. (See MILITARY EDUCATION.)

The United States Naval Academy at Annapolis, Md., established in 1846, is a national college for the training of officers and engineers for the navy. The Naval War College in Rhode Island and the Naval Training Schools in California, Rhode Island, and on the Great Lakes are also forms of education for the navy maintained by the National Government. The total appropriation for all of these institutions was \$1,028,094 in 1910. (See NAVAL EDUCATION.)

Under the Interior Department.—This department maintains a number of educational institutions. The United States Bureau of Education (*q.v.*) is under this department, as well as the Bureau of Indian Affairs. The United States Bureau of Education has charge of the educational work among the Indians of Alaska (*q.v.*), and the Bureau of Indian Affairs has control of the large number of Indian schools maintained by the National Government in the different states. With one exception these schools are located in the Central or Western states. The appropriation for education in Alaska in 1910 was \$200,000, and the appropriation for Indian education in the United States was \$4,566,021.97. (See special article on INDIAN EDUCATION.)

For a statement of the nature of the educational organization in our island possessions, and the amount of national aid granted, see special articles on the school systems of HAWAII, GUAM, PHILIPPINES, and PORTO RICO.

It will be seen from the above that the educational activities of the National Government have never been organized into any system, but scattered among the different bureaus at Washington, with the result that there is little system or coördination of the educational work of the National Government. In most cases Congress has done its work independently of any organization or advice. E. P. C.

NATIONAL HOME READING UNION,

ENGLAND.—An organization founded by the late Dr. J. B. Paton (*q.v.*), largely influenced by an article of Bishop Vincent's on "Chatauqua, a popular University," which appeared in the *Contemporary Review* in 1887. The Union was definitely organized in 1889. The purposes in view, as stated in Sadler, *Continuation Schools in England and Elsewhere*, were as follows:—

- (1) To stimulate, encourage and direct home reading in such a way as to make home reading educational in the truest sense of the word.
- (2) To give definiteness, continuity, and system to home reading, and to adapt it to the divers needs and tastes of readers.
- (3) To give all practical help, in the most economical and efficient way, to those who engage in such reading.
- (4) By means of local unions, or associations of readers, and the influences of a large organization, as well as by personal sympathy, to sustain the interest and confirm the purpose of all who undertake a regular course of home reading, and to unite them in honorable and helpful fellowship with each other.

The reading is arranged in three courses: Young People's Section, General Section, Special Supplementary and Introductory Courses. Two magazines, the *Special Courses Magazine* and the *General Course Magazine*, appear monthly and contain articles on books or subjects of interest, reviews, questions, and news. The Union sends out suggestive lists for reading with books of reference available in local libraries, "in art, history, social and political economy, poetry, science, exploration and all the sides of human activity dealt with in literature." The N.H.R.U. encourages the formation of local reading circles for study and discussion of books, and gives assistance to members by correspondence. It seeks to secure the coöperation between teachers in schools and the libraries, and the formation of reading circles among the senior pupils in public schools. The Board of Education in 1905 issued circulars calling upon local educational authorities to pay the expenses of and librarians to aid the organization of reading circles. Many schools and school systems are in active

coöperation with the Union, and have adopted its list of readings and have formed reading circles; among these may be mentioned the London County Council, Manchester, Leicester, Glasgow, and many county authorities. Another phase of the work of the N.H.R.U. is the summer assemblies. For a few years its annual meeting was held for ten days at Blackpool. In 1892 a removal was made to Bowness and the Lake District, and since that time the assemblies have been held at points of literary or historic interest, connected in the main with the reading of the year. The Union is associated with the Home Music Study Union. For the purpose of encouraging the wise use of holidays the N.H.R.U. also co-operates closely with the Coöperative Holidays Association (*q.v.*), and many other associations for adult education.

NATIONAL MONEY GRANTS.—See NATIONAL GOVERNMENT AND EDUCATION; SCHOOL FUNDS, PERMANENT.

NATIONAL SOCIETY, ENGLAND.—The success of Joseph Lancaster (*q.v.*) in establishing unsectarian schools, especially after the formation in January, 1808, of a committee to help him, stimulated the bishops of the Church of England to the formation of an association for promoting the establishment of sectarian schools. Lancaster's schools attracted public attention by the novelty of the monitorial system on which they were conducted, and public support by the cheapness which that system rendered possible. In Andrew Bell (*q.v.*) the Church had ready to hand a clergyman eager to be employed in organizing monitorial schools that should rival the others in attractiveness and cheapness while excelling them in orthodoxy. The vague ideas of the bishops were made definite and given a practical direction by a sermon which Herbert Marsh, Lady Margaret Divinity Professor at Cambridge, preached in St. Paul's Cathedral on June 13, 1811.

On Aug. 27, 1811, "a number of gentlemen, friends to the Establishment," met to discuss the question of forming a society, and at a larger meeting held on October 21 the "National Society for promoting the Education of the Poor in the Principles of the Established Church" was actually formed. The Prince Regent (afterwards George IV) "graciously consented" to be the patron, and the Charter of Incorporation, granted in 1817, prescribed that the Archbishop of Canterbury for the time being should be president, and the vice-presidents the Archbishop of York, all the bishops, and ten other persons being either temporal peers or privy councillors.

No time was lost in getting to work. At the end of 1812 the society could report that, with its help and encouragement, 52 schools attended by 8620 pupils had been opened. Next year there were 230 schools with 40,484 pupils. To provide the necessary teachers a model school was started on Holborn Hill, but this was soon supplanted by a much larger one in Baldwin's Gardens, Gray's Inn Lane. Intending teachers did little more there than master the mechanism of the monitorial system, but in the course of years the need of a more thorough training became evident, and the society opened five colleges, three of which (St. Mark's, Chelsea; St. John's, Battersea; and Whitlands, Chelsea) are still in existence.

In 1833 government grants were first given towards the building of schools; in 1846, towards the payment of pupil teachers and the maintenance of training colleges; and in 1853, toward the maintenance of schools. Profiting by these grants in aid of local effort and the local effort which they evoked, the society continued to extend its operations; in 1870 there were 6382 Church schools with an average attendance of 844,334.

By the act passed in 1870, if in any district sufficient school accommodation were not provided by voluntary agencies, a school board must be elected to supply the deficiency at the cost of the district. As board schools would necessarily be unsectarian the National Society made a mighty effort to render them unnecessary by establishing Church schools. The task was too great for the effort to succeed altogether, but it was far from failing altogether; there were in 1902 11,711 Church schools with an average attendance of 1,927,663.

Part of the cost of maintaining both board and voluntary schools had come out of parliamentary grants; the remainder for board schools came out of rates, and for voluntary schools out of subscriptions. The act of 1902 abolished school boards, made the councils of the counties and county boroughs the local education authority, and gave all schools the same support out of rates without depriving the voluntary managers of their power. Some of the councils, objecting to paying toward schools which they were not allowed to control, tried to differentiate in various ways between them and the council schools. The National Society fought the battle of the local managers and by a series of decisions in the law courts obtained equal treatment for their schools.

In 1911 there were 10,952 Church schools with an average attendance of 1,750,094 as against 8006 council schools with an average attendance of 3,962,819. The average council school is thus obviously larger than the average Church school, the reason being that many of the Church schools are in rural parishes and many of the council schools in towns or urban districts.

NATIONAL TEACHERS' ASSOCIATION.

—See TEACHERS' VOLUNTARY ASSOCIATIONS.

NATIONAL UNION OF TEACHERS, ENGLAND.—The largest organization of teachers, primarily those engaged in elementary school work, in England. The Union was founded in 1870 as the National Union of Elementary Teachers, but the present title was adopted in 1889, making the association more comprehensive. Among the objects of the N.U.T. in addition to the safeguarding and protection of the interests of members, are the following:—

To improve the condition of education in the country and to obtain the establishment of a national system of education, coordinated and complete, also to secure for all public elementary schools adequate financial aid from public sources, accompanied by suitable conditions.

To afford to the Board of Education and to local authorities for education, and other organizations—public or private—which have relation to educational affairs—the advice and experience of the associated teachers.

To secure effective representation of educational interests in Parliament.

To raise the qualifications and status of teachers and to open to the best-equipped members of the profession the higher posts in the educational service of the country, including the inspectorate of schools.

A Teachers' Provident Society and Teachers' Benevolent and Orphan Fund are maintained. A representative of the Union is supported in Parliament. Legal advice and assistance are given to members. Through an Examination Board the Union issues Teachers' Diplomas in music, manual training, needlework, and dressmaking. The N.U.T. has exercised and continues to exercise considerable influence on the administration of elementary education, the training of teachers, and improvement of codes and regulations, and teaching methods. The membership of the Union in 1910 was 69,073 distributed among 516 local branches, which in turn are grouped into fifty-seven county associations. The membership is gradually being extended among other than elementary teachers. The *Handbook of Education*, *The Red Code* (annual) are published by the N.U.T., while the official organ of the Union is the *Schoolmaster* (weekly). Sir James H. Yoxall, M.A., M.P., is the secretary.

NATIONAL UNIVERSITY.—The establishment of a national university, created and supported by the federal government and located at the national capital, has been repeatedly proposed and much discussed since the idea was first definitely expressed in 1790. The interest of George Washington was keen and persistent in the proposal to found a federal institution to which American youth would come for their higher education instead of seeking it in Europe, and in which would be gathered students from all parts of the United States, thus fostering that common national feeling which he had seen developed in the Continental army during the Revolution. He referred to the matter of a national university in his first message to Congress, and in his will he gave fifty shares in the Potomac Company, worth at that time about \$25,000 toward the endowment of such an institution, provided Congress should "incline to extend a fostering hand toward it." This act Congress has never been persuaded to perform, though urged to do so by Madison, in three messages, by John Quincy Adams and later presidents, and by many other statesmen.

The question of constitutionality was early raised in connection with the proposed establishment. As a "loose constructionist," Washington did not doubt the power of the federal government to provide such an institution; Jefferson and his party took the opposite view, and a congressional committee in 1811 reported that it would be unconstitutional for Congress to found, endow, or control such a "seminary." Even before broad interpretation of the constitution finally triumphed, the practice of Congress in voting money for the establishment and support of the military academy at West Point and the naval academy at Annapolis, and in granting lands to Georgetown University and Columbian University in the District of Columbia, went far to settle the theoretical question of power. A senate committee, first a special "committee to establish the University of the United States" to consider a bill introduced by Senator George F. Edmunds in 1890, and later a standing committee, reported in favor of the creation of such a university in 1893, 1894, 1896, and 1902.

Numerous bills for establishing a national university have been introduced into Congress, some of them widely indorsed by college presidents as well as by statesmen, ecclesiastics, and professional men. The arguments against the proposed institution have been based on belief in its undesirability rather than the lack of constitutional power to create it. In 1899 a committee of fifteen "on the national university project," organized by the National Education Association and including the presidents of Harvard, Chicago, Cornell, Illinois, North Carolina, Michigan, and Washington and Lee universities, agreed unanimously that the federal government should aid, but not con-

trol, the educational agencies of the country, that none of the bills presented in Congress was entirely commendable, that "the government is not called upon to maintain at the capital a university in the ordinary sense of that term," and that the most that should be attempted was systematic cooperation in the use of the opportunities for advanced instruction and research offered by the departments and bureaus in Washington.

The arguments for the national university are stated strongly in the appeal of the "national university committee of four hundred" in 1907, in resolutions of the National Education Association, and in the bill proposed by an almost unanimous vote of the National Association of State Universities in 1907. They assume that it is to be a purely graduate institution, cooperating with other universities and colleges, and with scientific departments of the federal government, conferring no degrees, or only the doctorate, and devoting itself wholly to higher instruction and research, to promote the advance of science, pure and applied, the liberal and fine arts, and the national welfare. They declare that it would vivify by its influence every part of the educational system of this country, greatly increase present opportunities without interfering necessarily with any now existing; attract both scholars and students from the widest possible range; enhance scholarship in many fields; and improve the service of the government; and that its right to determine what institutions should be recognized would raise and make uniform the standards of collegiate institutions in the United States without requiring conformity to particular methods or schedules. Much of the equipment ordinarily required for the highest forms of research already exists in Washington through congressional appropriation. The Library of Congress, with 1,500,000 books and pamphlets, and other libraries in departments, numbering almost as many pieces more, including duplicates of those in the Library of Congress; great collections of the National Museum, the Smithsonian Institution, the Medical Museum, the Patent Office, and the Corcoran Gallery; magnificently equipped laboratories of bureaus, such as those of Standards and of Chemistry; the great observatories; the Geological Survey; and opportunities for field service under the most expert direction in every part of the country,—all these are instrumentalities which might be utilized in considerable degree, without interference with their proper service to the public and to the government, by a national university, wisely organized and judiciously directed for instruction and for research. In fact, Congress in 1892 and 1901 opened up the government departments for the purposes of advanced research. It is estimated that the equipment and apparatus thus available represents a valuation of not less than \$60,000,000.

Something akin to the organization of facilities for research and instruction here contemplated is already carried on in a very limited, and often incidental, way in the medical schools of the Army and Navy, in the Public Health and Marine Hospital Service, in the bureaus of Standards, Statistics, Plant Industry, Soils, Fisheries, Entomology, and Public Roads, and in the National Botanic Gardens. Certain work done in some of these offices or laboratories has been accepted in partial satisfaction of the requirements for a degree by some of the strong graduate schools. C. K. B.

NATIVISM. — A term applied to the theories according to which the foundations of all knowledge, or else the essential conditions of some branch of experience, are born in or with the mind or agent. It thus has close associations with the terms *a priori*, innate ideas, and intuition (*q.v.*). In psychology the term has come to be applied particularly to those theories which hold that the extensity of space perceptions is an original, native element in some at least of the sensational qualities, in opposition to those theories which hold spread-outness and depth to be the results of association among qualities themselves lacking spatial quality. The most recent use of the term has been much influenced by modern biological theories of heredity. The old *tabula rasa* conception of sensationalistic empiricism has been made an anachronism by the demonstration of the number and variety of the instinctive non-acquired tendencies. It is only by a figure of speech, however, that these tendencies can be said to be innate in the *mind* — being rather connate with the organism. This conclusion involves quite as complete a reconstruction of the older type of nativism as of the older type of empiricism. The educational importance of the controversy gathers about the question of the relative importance of Nature and Nurture — the relative importance and function of the hereditary tendencies of the organism as compared with the influence of the social

and cultural environment. (See HEREDITY.) This question is thoroughly misconceived, however, when treated as a problem of one versus the other. The conditions of the educative growth of an individual are ultimately inherent in the organism, possessing its native tendencies to act and to be susceptible. This fact is all-important in contrast with the belief of a number of eighteenth-century theorists that practice and the influence of economic and political conditions are omnipotent. It is also highly important in showing the necessity of recognizing individual differences of capacity and aptitude. But, on the other hand, the direction given these native powers, the kind of ends for which they become effective, the ways in which they are used depend upon nurture—that is, upon the influence of the social medium consciously and unconsciously exerted. J. D.

NATORP, BERNHARD CHRISTOPH LUDWIG (1774–1846) — German educator, the son of a Protestant clergyman, born at Werden in the Rhine province. He studied theology and pedagogy at the University of Halle under A. H. Niemeyer (*qv*). In 1798 he received a call as a preacher to the city of Essen, and there took a leading part in the reform of the schools, which were reorganized in accordance with his *Grundriss zur Organisation allgemeiner Stadtschulen* (*Plan of Organization of Common City Schools*, 1804), a work based on the principles of Comenius, Rousseau, and Pestalozzi. From 1809 to 1816 he supervised the schools of the province of Brandenburg, where he did much for the improvement of methods and the education of teachers. In 1816 he returned to Westphalia and for thirty years more remained active in directing the educational and ecclesiastical interests of the province.

His most interesting educational work is his *Briefwechsel einiger Schullehrer und Schulfreunde* (*Correspondence of some School Teachers and Friends of Schools*, 1811–1816), in which he develops his pedagogic principles in the form of personal letters between schoolmen. Another work that may be mentioned is his essay on Bell and Lancaster (1817), in which he shows the superiority of the German elementary school, founded on the principles of Pestalozzi, over the much-advertised Bell-Lancasterian monitorial system. NATURAL HISTORY.— See NATURE STUDY; ZOOLOGY.

NATURAL METHOD.— The term “natural” has been applied descriptively to meth-

ods of teaching in many subjects, frequently as a trade name for textbooks with a particular system of instruction that supposedly avoid artificiality. The term is applied when one of two characteristics is assumed to be present in the procedure suggested: (1) When the method is psychologically based,—i.e. takes account of the instincts and normal interests of young children,—it is said to be natural. Such a natural method is opposed to one which is mentally artificial. If words used in spelling are selected and graded according to the needs which develop in the course of the child's attempt to express his own experiences, the method is said to be natural. If the words are chosen and arranged merely from the standpoint of their frequency of usage in adult life, and without regard to personal motivation, the method is artificial. (2) When the method utilized conforms to usual procedure in social life, omitting special pedagogical devices peculiar to schoolroom practice, it is called a natural method. Thus it is contended that full written or oral computation of problems in arithmetic is an unnatural method; while a combined written and mental method of computation is said to be a natural procedure. In recent years the reaction against artificiality of school procedure of every sort has been marked. Teaching practice has tended more and more to take account of psychological lines of least resistance and to avoid modes of work which differ greatly from social practice. Hence naturalistic methods have characterized teaching reform in all the school subjects. H. S.

NATURALISM.— See HUMANISM AND NATURALISM.

NATURE.— Probably no philosophical conception has had a more general or widespread

popular influence than that of nature. Its intellectual career has been facilitated rather than hindered by the variety and ambiguity of senses attached to the term, especially as regards the things to which it has been set in opposition. Recognition of the rôle of this uncertainty in enhancing the influence of the idea is not necessarily cynical or skeptical in character. The more typical senses of the term are sufficiently near to one another so that they insensibly pass into each other; while among the more fundamental ideas operative in human history have some vagueness attaching to them, because they stand for deeplying practical aspirations and for intense emotional attitudes as well as for rational notions which may be accurately defined. The function common to the differing senses of the term nature has been the demand for some standard or norm for the regulation and valuation of human beliefs. It designates whatever is taken to be intrinsic and inevitable in existence and thought, in antithesis to what is external, artificial, and factitious; leaving it to the culture of the time to determine just where the natural, the normal and normative shall be looked for, and just what, in contrast, shall be regarded as secondary and accidental.

The classic conception of nature, as fixed by Aristotle, was an aftergrowth (and to some extent an outgrowth) of the inquiry raised by some of the sophists as to whether religion, morality, and the State exist by nature, or by mutual agreement (convention, tacit or express) or by decree, by enactment of superior authority. This led to an inquiry after the true nature of things, their real essence. Etymologically, φύσις, the Greek word translated "nature," was derived from the verb "to grow," just as the Latin *natura* is from the verb "to be born." Aristotle identified the nature of a thing with the thing in its full or completed growth, which is also the thing in its state of fullest activity or actuality. The nature of an acorn is the oak; the true nature of the human body is the intellectual activity in which the organic processes are most fully realized; the nature of the individual is the state in which alone distinctively human properties (in contrast with those of brutes and gods) come to realization. The distinguishing trait of nature is that the process of realization, involving the four ultimate principles or causes (*q.v.*), takes place from within, in contrast to art (all products of human invention and skill), where the movement is initiated from without. This metaphysical and teleological conception of nature was taken up into patristic and scholastic philosophy. The Stoics retained much of the Aristotelian idea, but conjoined it with the popular sense of nature as the sum total of laws, processes, and events that constitute the world as an organized whole or cosmos, — hence the precept of life in accordance with nature as the supreme moral precept. Through the

influence of the Stoics upon jurisprudence, the conceptions of a "state of nature," "natural law," and "natural right" were introduced as affording the norm of eternal justice in distinction from the positive institutions and civil laws which represent the adaptation of this eternal law to temporary and local conditions.

In modern times the conception of nature was first affected by the rise of physical science. It meant the sum total of laws which "govern" natural phenomena. Sir Isaac Newton considered these laws to present the divine legislation for the realm of created things, expressions of a rational will, so that nature might almost be conceived as a divine vice-regent. This meaning was taken up by the Deists and made the basis of a criticism of the miraculous and the supernatural in religion. As the influence of this mode of thinking spread into France, the conception of nature was generalized and made an implement of criticism of everything in the Church and State that appeared to the *philosophes* to be irrational. Since these social institutions were historical products, it is hardly too much to say that the term nature as a eulogistic term was put into opposition to history, and to everything whose existence depended upon historical traditions rather than upon an enlightened reason.

Rousseau agreed with the rationalists in opposition to existing social institutions as artificial and so unnatural, but attacked the philosophers of the enlightenment by including art and science as themselves artificial, sophisticated, and misleading. Nature, according to him, was not to be looked for in conscious reason, but rather in primitive, instinctive, unreasoned impulses and emotions. The natural is the original in the sense both of the primary in time and the creative, the origina-tive. The "return to nature," that concept so influential in educational philosophies if not in school practice, was a return to the primitive untaught sources that condition all teaching. While there was much in Rousseau which would lead his followers to interpret the natural as an idealization of the life of savages into a poetic idyl, there was also much to call attention to the original instincts and principles of growth in children. Through the influence of Rousseau upon Pestalozzi, Froebel, and others, education in accordance with nature came to mean that there were certain intrinsic laws of development or unfolding, physical, mental, and moral, in children, and that these inherent principles of growth should furnish the norms of all educational procedure.

Meantime, the attacks by Rousseau upon civilization in the name of nature called out not merely the interest of Romanticism in picturesque natural beauty untouched by human hands, in folklore, primitive arts and poetry and in peasant life (as more primitive, unsophisticated and unconsciously creative), but also that phase of German philosophy which de-

liberately set itself to justify culture as being more truly natural than crude nature and than original impulse and instinct. This tendency found expression in all of Goethe's later work, as well as in the philosophers, Kant, Fichte, and Hegel, and in Schiller's conception of art as the great civilizing and moralizing agency of humanity. The same movement led to the idea that the nature of man is found in humanity, rather than in the individual; and hence to an idealization of history, since it is in history rather than in the consciously evolved ideas of an individual that humanity is revealed. This movement culminated in Hegel's theory that social and political institutions in their historic manifestation are more truly real than either phenomena of the physical world or the moral efforts of individuals in their individual capacity—that indeed the entire education of the individual consists in effecting in him an assimilation of the spiritual products of humanity in its historic evolution as a progressive realization of spirit. In this way, the criticism of Rousseau's return to nature reached its climax in a wholly antithetical theory. J D.

See **CULTURE**; **HUMANISM AND NATURALISM**; **ROUSSEAU**.

NATURE STUDY.—A term which within two decades has come into prominent use in America and England to designate certain studies of natural things, particularly in schools of elementary grade. Also, in a much more limited usage, nature study means popular study of animal or plant natural history outside of schools by children or adults. The term has been applied chiefly to elementary studies of living things; but within recent years many lessons dealing with inorganic nature have been introduced into the nature study of elementary schools. As a matter of convenience, some writers distinguish between biological nature study for living things and inorganic or physical nature study including lifeless objects and the processes of heat, light, etc.

The term nature study was for many years criticized, because etymologically it suggests all scientific studies of nature, and hence is coextensive with the combined natural sciences; but this objection is no longer urged by prominent scientists, for it is now generally understood in both England and America that nature study means a special type of study adapted primarily to pupils of elementary school age.

The fact that nature study and natural science deal with the same objects and processes has led to much investigation and discussion of possible differentiation in educational practice. It is now agreed among the leaders of the nature-study movement that a satisfactory division of the field between nature study for elementary schools and science courses for higher schools has been found in theory and is rapidly becoming successful in practice.

Briefly, this differentiation is along the following lines: Science, in the strict sense, is concerned with knowledge organized under principles or generalizations, *e.g.* evolution, cell doctrine, and other principles of biology, atomic theory of chemistry, and conservation theories of physics. The best science courses in high schools and colleges are now presented so as to set forth the fundamental principles, and the natural materials are studied chiefly as illustrations of principles. In short, the present-day courses in science revolve around the principles which lie at the very heart of organized knowledge.

Now, most of the great principles emphasized in courses of science in high schools and colleges are admittedly beyond the mental grasp of elementary school children. This is one suggestion looking towards differentiation, and it has proved the most useful. Nature study, independent of the generalizations which characterize science in the strict sense, has come to deal with nature as it touches our daily lives directly. Here, then, are the essential differences between nature study for elementary schools and science for higher schools: (1) the material for study may be the same; (2) the observational method of study differs only in degree of advancement; (3) but the point of view is radically different, for science aims primarily at scientific principles, while nature study avoids these and deals with natural things and processes as they directly concern daily life. Of course, science study of the "applied" type does not eliminate every-day human interest, but this is reached somewhat indirectly in that the first aim is for principles, and, secondarily, these are applied to practical life. It is most useful in practice, however, to recognize that nature study for elementary schools and science for higher schools differ chiefly in that nature-study lessons are not organized with direct reference to the characteristic principles of science.

Nature study, however, should not be unorganized and without continuity of lessons, that is, mere object lessons of the old type. It may be independent of the organization of science and still have an efficient organization for educational ends. For example, a study of useful trees and elements of forestry may be educationally organized for pupils who are too immature to comprehend the principles of botany.

It should be noted that there can be no sharply defined line between nature study and science so far as practice in our school system in its entirety is concerned. In the upper elementary grades and first year of the high school the best nature study gradually leads the way into more and more advanced lessons which are designed to point directly to the great generalizations of science. But the line can be drawn sharply enough for all practical purposes, and there is no longer any sufficient excuse for duplicating in nature study

the work already well done as science in high schools.

The distinction between nature study and science may be summarized in the following definitions: "Nature study is primarily the simple observational study of common natural objects and processes for the sake of personal acquaintance with the things which appeal to human interest directly and independently of relations to organized science. Natural science study is the close analytical and synthetical study of natural objects and processes primarily for the sake of obtaining knowledge of the general principles which constitute the foundations of modern science."

As to the educational values of nature study, it is now commonly recognized that they relate to discipline and information; discipline in habits of thoughtful observing, and information which has æsthetic, moral, practical, and intellectual influence in the every-day life of the average individual. To develop these values the teaching should be directed by certain definite aims; and summarizing the predominating tendencies of the present time, the great aims are in essentials as follows: (a) To give pupils general acquaintance with and interest in common objects and processes in nature. (b) To give the first training in accurate observing as a means of gaining knowledge direct from nature, and also in the simplest comparing, classifying, and judging values of facts: in other words, to give the first training in the simplest processes of the scientific method. (c) To give pupils useful knowledge concerning natural objects and processes as they directly affect human life and interests.

There is quite general agreement that there is one fundamental method of teaching nature study that consists in getting the pupil to see and think for himself, and this is observation in the scientific sense. Upon this depend two of the three aims above stated, the aim for sympathetic acquaintance and the aim for training in methods of observing. Books and lectures cannot suffice for these, as possibly they might for giving useful information. There is now little dissent from the proposition that true nature study cannot be primarily book study. Rather should nature study aim to make the pupil learn to study nature in the absence of books, thus preparing for the usual condition in our every-day life. But although emphasizing observation as the essential basis of nature study, it is coming to be accepted widely that books for supplementary study are desirable. This refers to elementary scientific books, and not to the so-called nature stories, fables, and poems, which may well be read and explained as part of correlated language lessons, but not as nature study.

With regard to the selection of materials for study, there is universal agreement that we should, first of all, select the most common and the most interesting from the viewpoint of

every-day life. The application of this principle is responsible for much of the apparent lack of uniformity in courses of nature study. The geographical distribution of natural things, particularly the living, is highly variable, and hence the selection of common things for nature study must vary.

Much study is now being devoted to the problem of organizing nature-study courses. The pioneer work was largely stimulated by enthusiastic scientists, some of whom went so far as to advocate entire freedom from organization; but gradually the subject is now coming under the influence of specialists in education who are applying the general principles accepted for all other phases of elementary education.

At present many science teachers are much interested in the problem of adding to nature study many studies of inorganic nature in correlation with the biological work, which has long been so prominent that many educators have regarded nature study as an elementary phase of biology. There is a widespread tendency in America towards making grammar school nature study largely inorganic. So far most of this has been called "elementary science," and is largely an extract from college physics and chemistry; but much dissatisfaction points towards reorganization from the standpoint of nature study. In addition to such inorganic nature study in one or two grammar grades, there is need of some simple problems on the same line in even the first primary grades.

School gardens have proved a very important phase of nature study, especially because they combine in such a natural way the animal, plant, and inorganic aspects of nature. Most school gardens which have well-developed educational aims are conducted in harmony with the established principles of nature study. (See GARDENS, SCHOOL.)

Perhaps the most important of the present problems of nature study in America is that of connecting physiology and hygiene with nature study. There is a widespread opinion that hygiene should be taught on the observational basis of nature study. The following will suggest some of the possible correlations between nature study and hygiene; but the details of the plan will necessarily depend upon the course in nature study. In nature study work with squirrels, rabbits, or other common animals, the form and uses of mouth, jaws, and teeth may be made to lead to comparison with human teeth, their use and their care. Thus all the elementary hygiene of the mouth cavity may be correlated with nature studies of animals. Likewise, the hygiene of human skin, hair, and nails may be connected with studies of these structures in various animals. The hygiene of clothing is naturally referred to in connection with nature-study lessons on the fur or wool of animals, possibly with silk and

cotton, and also with lessons on heat in the inorganic nature study. The useful hygiene of the eyes and ears may be introduced in connection with simple experiments with light and sound. The question of food, which is so prominent in elementary books of hygiene, may be associated with lessons in domestic science, and also with nature-study lessons on animals and plants which are used for human food. These are simply suggestions of possible correlations which would involve the most valuable hygienic teaching in the elementary schools. Such correlations would undoubtedly make the hygiene vastly more interesting to pupils, and at the same time avoid a separate time assignment. It is doubtful whether there is any hygiene useful for pupils in any of the first six or seven grades of the elementary school which it is not possible to bring into close relation with biological and physical nature study.

Concerning the relation of nature study to geography, it is obvious that the two subjects touch in the home, industrial and physical aspects of geography. The nature study of the earliest grades should include topics which will pave the way for home geography. The first formal work in geography usually relates to the home environment, and, in so far as the observational method is used, such home geography is good nature study. Moreover, the nature study of the same year should center around topics especially related to homes, such as ornamental plants, building materials, simple sanitation, and local food-supply.

Many of the topics in the industrial aspects of geography suggest correlations with nature study. For example, fisheries, lumbering, agriculture, and mining, in industrial geography, suggest nature study of certain aquatic animals, lumber-producing trees, elementary gardening, and elementary mineral studies. Finally, the physical aspects of geography demand correlation with inorganic nature study. For example, weather studies on an observational basis are good nature study; and experiments with air, water, light, heat, and electricity are needed in correlation with physical geography. The geography of foreign countries offers no useful opportunities for correlation with nature study, which deals primarily with the home environment. Lions, tigers, plants producing tea and coffee, and other foreign materials had better be observed as illustrative of geography lessons.

The recent movement in America towards industrial education has resulted in much agricultural instruction in rural schools of elementary grade. In some places it has been called "agricultural nature study"; in others, "elementary agriculture"; and in still others "nature-study agriculture." Elementary agriculture tends to be a weak imitation of the vocational aspect of high school agriculture; while agricultural nature study or nature-study

agriculture is practically nature study including many natural things connected with agriculture. The nature-study point of view is most desirable in the elementary agricultural teaching. It is commonly admitted that in the first six grades agricultural nature study should deal with the common things of country life, but from the viewpoint of general nature study which is not limited to the utilitarian aspects of agriculture. With regard to the grammar grades of rural schools, there is a strong movement towards including the elements of agricultural science. This is open to criticism because its vocational value for young pupils is doubtful, it presents only the commercial side of country life, it displaces hygienic and chemico-physical studies of great value to all grammar school pupils, and as general education is inferior to advanced lessons from the general field of nature study.

In America, nature study in the widest sense is fostered by the American Nature Study Society, founded in 1908 and with about one thousand members, including all educators who are prominently identified with the movement. The *Nature Study Review*, founded in 1905 and "devoted to all scientific studies of nature in elementary schools," is the official journal. In England the School Nature-Study Union, organized in 1903, publishes *School Nature-Study*. M. A. B.

NAUTICAL SCHOOLS AND ACADEMIES. — See NAVAL EDUCATION; SEAMANSHIP, TRAINING FOR.

NAVAL EDUCATION. — That form of education which fits officers and men for service

in the navy. While it embraces also nautical education, the latter relates mainly to peaceful pursuits on the sea. The principal commercial lines arrange for the training of their young officers in the vessels of the regular service, or in some cases in school ships; and there exist in some of the states, as a part of the local school system, school ships in which young men are trained for the merchant marine. The technical schools and colleges also provide courses in such subjects as nautical astronomy and navigation, and in all branches of marine engineering. In this article only that form of naval education which equips officers and enlisted men in the navies of the chief countries will be dealt with.

United States. — *Enlisted Men.* — The main body of the naval force consists of the enlisted men. In early days their education was simple. A merchant sailor was quickly at home in a man-of-war. The sails and rigging were generally similar to those in a merchantman; and the ordnance of the day did not present any difficulties that could not be mastered after a brief apprenticeship. In a modern man-of-war, however, while the engines and boilers may resemble those of a liner, the ordnance and other mechanisms are complicated in the extreme and need the services of a highly trained personnel. With progress in machinery and gunnery it was seen that the enlisted men would need to be trained in their specialties. The enlistment of boys as naval apprentices was undertaken before the Civil War, but the early attempts to establish a training system did not prove successful. A reason frequently assigned for early failures was that although the hope was held out to the boys that they might win a commission, only few did so, and the rest were disheartened. A way should always be open for subordinates to rise, but this should not be held out as the main inducement in the training of seamen.

The present system dates from 1875 afloat and 1881 on shore. The early idea was to embark the boys in cruising training ships and there give them the rudiments of a man-of-war's man's education. Later a shore headquarters was established at Newport, where the boys were received, and from which they were transferred to the cruising ships for further training. Then came a parallel system of training for landsmen, with entry at eighteen, the apprentice boys entering as young as fourteen. The landsmen spent only a short time at the training station and were then drafted to general service. The present system is an evolution or development. It combines in a measure the two earlier ones. The recruit is received as early as seventeen and is called an apprentice seaman. He serves about four months at the training station, where he is given preliminary instruction. The cruising training ships have now entirely disappeared from the system, the apprentice seamen going from the training

stations directly to general service. Besides Newport, there are now training stations at Norfolk, San Francisco, and North Chicago.

The instruction of the apprentice seamen at the training stations is necessarily elementary. The recruit is put into uniform, taught neatness and cleanliness in person and clothing, learns to sleep in a hammock, to pull an oar, to box the compass, heave the lead, also a certain amount of knotting and splicing, signaling, boat sailing, swimming, the sails and rigging of a ship, gunnery, infantry drill, and last, but not least, discipline. After leaving the training station and joining a cruising ship, the education of the apprentice seaman is entirely practical. He learns his duties in the main by doing them and seeing others doing similar duties, though all the men are under the supervision of, and are instructed in their duties by, their officers. When qualified, he is promoted to higher ratings.

Artificer and Special Branches. — In addition to the seaman branch, there are the artificer branch, which includes the machinists, firemen, electricians, carpenters, and the like; and the special branch, which includes yeomen (writers), the hospital corps, stewards, cooks, bakers, musicians. The specialty classes at one or more of the training stations include yeoman classes (correspondence and accounting), musician classes, schools for hospital apprentices and for cooks, bakers, and commissary stewards. These schools are entirely practical, the methods and appliances being identical with those to be found on board ship.

It is thus seen that opinion has varied in the past as to the advantage of one or other of two systems, the first a special training of some length, in cruising training ships; the second, a short stay at a training station, for organization and rudimentary training, with completion of the training in the ships of the regular service. Whatever the merits of the two systems, the second is largely the method in the civil trades; but the controlling reason in any case is that the first system requires too large a training service, perhaps as many as thirty special ships, which is prohibitive. The navy itself is now the training school.

In addition to the training system as above described, there are several service schools for enlisted men. The seaman gunners' class is made up annually of deserving men in their second enlistment and under thirty years of age. One branch of the class is at the Gun Factory in Washington, where instruction, combined with practical work, is given in ordnance and mechanisms. The other branch is at the Torpedo Station at Newport, where the men are instructed in torpedoes and diving. These courses last six and eight months, respectively, the graduates becoming gunner's mates.

The electrical school is at New York. The course here is about five months, and includes the theory and practice of electricity and elec-

trical mechanisms and of wireless telegraphy. Besides class work and lectures the students engage in practical work in the shops. The appliances are similar in all respects to those to be found on board ship.

The machinists' school is at Charleston, S.C., and is made up of deserving men under thirty years of age who have mechanical knowledge or have shown mechanical ability. There are two classes, according to the knowledge and requirements of the men. The course includes bench work, practice with machine tools, and running and repairing marine engines. It lasts about sixteen months.

Artificers' schools give practical instruction to carpenter's mates or shipwrights, blacksmiths, plumbers, painters, and ship fitters. The subjects include the practical work of these several trades, in which the men have already had some experience and practice. The course lasts for three months.

From the above, the instruction of enlisted men is seen to be on a very satisfactory basis. Recruiting is not difficult, owing to the benefits offered and to the fact that the positions are open to landsmen as well as to men with nautical knowledge. On leaving the service, the ex-sailors are sought after in civil occupations, as they have all acquired knowledge which is as useful in civil life as in the navy. The time spent in the navy is thus a true training in character, resourcefulness, and knowledge, and is of advantage to the country and would be desirable entirely apart from the service rendered by the navy.

Officers.—The education of officers offers problems of a far more serious nature than that of enlisted men. The line of the navy may be taken up at first. Line officers enter as boys, midshipmen, with the intent of making a life career of the navy. In old times they received their appointments at an early age, from twelve to fifteen, and went at once to a cruising ship. Here they picked up readily all manner of practical information about the ship, but had no thorough grounding in general education or in the higher arts of their profession. The instruction they obtained in the service was scant, and, besides that received from the schoolmaster, if there was one on board, was due in the main to the kind-hearted interest perhaps of the chaplain or of the older officers. Their advancement in knowledge depended mainly on themselves, and it is to their everlasting credit that they developed into the characters that make up our early naval history.

The Naval School at Annapolis, was established in 1845 by George Bancroft, the historian, at the time Secretary of the Navy. The object, in his own words, was "to collect the midshipmen who from time to time are on shore, and give them occupation during their stay on land in the study of mathematics, nautical astronomy, theory of morals, international law, gunnery, use of steam; the Spanish and French

languages, and other branches essential in the present day to the accomplishments of a naval officer." The title of the school was changed in 1850 to the United States Naval Academy, which it has since retained.

Midshipmen entered the school originally at from 13 to 17 years of age. This was changed later to 14 to 18, then 15 to 20, and is now 16 to 20. These last ages are generally regarded as too old, and the range is too great. It is proposed now to make the entrance ages 15 to 18.

The earlier classes of midshipmen had already been at sea when the school was established, but it was found more satisfactory later to enter them at the school, where they were retained for one or two years, followed by three years at sea, then one or two more years at the school. This plan was not followed for long, and gave way to the system of four continuous years at the academy. The summers were given up alternately to practice cruises and leave of absence. This is still the general plan, though since 1873 the course has been six years, the last two at sea in ships of the regular service, with a final examination at the end of the six years. In 1912 the course was changed back to four years, at the conclusion of which the midshipmen are commissioned in the regular service.

The best method of educating midshipmen has been the subject of much discussion. Had ideas on education in general been more settled, it might have been simpler to establish a satisfactory course at the Naval Academy. Education develops the mind and character and also imparts information. This information may be either generally useful in life, or useful in some walk of life. If the latter, it may be designed to cover the whole field of the vocation, or it may simply fit the student to begin life in that particular field. These considerations all affect the character of the Naval Academy education, and the weight given at various times to one or the other of the acknowledged objects has produced corresponding variations in the subject matter of the course. All admit the necessity of developing mind and character, and there is sufficient unanimity on the subjects to be required in the earlier years of the course to satisfy a general education. There remains the proper division of theoretical and practical subjects included in the naval profession between those covering the whole field and those required to fit the midshipman to begin his life in the navy. To this question is due whatever diversity of practice that has existed in the past. Such will also probably be the case in the future.

The following consideration must be borne in mind. The young officer must be prepared to begin his career aboard ship. To develop into a successful naval officer he must study all the rest of his life. He should learn the rudiments of the whole profession at such time as he has the opportunity to pursue a systematic course,

that is, at the Naval Academy. He should learn thoroughly the duties he will have to take up on graduation. The time that can be devoted to the course at the Naval Academy is limited. If criticisms have been made at any time, it is that possibly too great an effort has been made to impart detailed knowledge that would be useful to higher officers, but could not be employed by a midshipman on graduation. And on the other hand, it is only within a few years that the subject of naval strategy has been included in any form in the course of instruction. Midshipmen are not expected to exercise naval strategy, but they are entitled at least to know that there is such a subject, before discovering it for themselves, if their inclinations lead them to the study of the art of war.

Another matter is the correct adjustment of the relative weight of theoretical studies and practical exercises. Many good practical officers in the navy have not been strong in studies. The navy needs both types, practical officers, and also officers capable of independent theoretical research, and it needs more of the former than of the latter. If a sufficient number of practical officers is developed, there will be inevitably among the number enough officers of scientific attainments to supply the needs of the navy. On this principle, a large weight should be assigned to practical exercises designed to develop the greater proportion of naval officers.

A correct utilization of the available time at the Naval Academy would require, therefore, thorough instruction in all the duties of the young officer, and, so far as the remaining time would permit, elementary instruction in every professional subject.

Candidates for the service are admitted to the Academy by nomination and on passing the required mental and physical examinations. Each senator, representative, and delegate in Congress is allowed two (after June 30, 1913, only one) midshipmen at the Academy; and five each year, appointed by the President, are allowed for the United States at large. One midshipman is maintained from Porto Rico by the President. Two entrance examinations are held each year. The mental examination covers punctuation, spelling, English grammar, geography, United States history, world history, arithmetic, algebra through quadratics, and plane geometry. The maximum mark is 4.00; the passing mark 2.50. No candidate is admitted without passing the physical examination before a board of three navy surgeons.

The present course at the Naval Academy includes the following:—

Mathematics, first two years, algebra, geometry, trigonometry, calculus, analytic geometry, spherical trigonometry, stereographic projection.

English, first two years, rhetoric, composition, literature, naval history.

Modern languages, first two years and last half of last year, French and Spanish.

Marine engineering and naval construction, whole course except first half year; mechanical drawing, mechanical processes, principles of mechanism, marine engines and boilers, naval construction, engineering mechanics, experimental engineering, gas engines, turbines.

Physics and chemistry, second year; elementary physics, chemistry, physics.

Seamanship, last two years; boats, ships, naval tactics, naval warfare, international and military law.

Ordnance and gunnery, last two years; infantry, artillery, gun drills, torpedoes, mines, elastic strength of guns, exterior ballistics, range tables, fire control, target practice.

Mechanics, first half of third year; theoretical and applied mechanics.

Electrical engineering, last two years; electricity, magnetism, electromagnetism, electrochemistry, direct and alternating currents, dynamo-electric machines, heat, power, light, wiring, testing, communications, devices and instruments, wireless telegraphy, and telephony.

Navigation, last half of third year and fourth year; astronomy, theory and practice of navigation, compass deviation, surveying.

Naval hygiene, first half of fourth year, effects of alcohol and narcotics, first aid to injured.

In addition to the instruction and recitations in the above subjects, which take place during the regular study hours, there are every afternoon of week days (mornings on Saturdays) drills and exercises in all professional subjects. These exercises include all the subjects that have been enumerated in the training of enlisted men, also the practical work of every sort that is performed by or comes under the supervision of officers in their daily duty aboard ship. This practical work is further supplemented by the summer practice cruise, in which all the midshipmen take part, with the exception of the new entering class, who engage in practical work at the Naval Academy. In 1912, for the first time, the two senior classes are embarked in ships of the regular fleet, the third class going in a practice ship as before.

The Naval Academy course thus gives officers a grounding in all the professional work of the navy. It does not train them to be specialists in the various subjects. This is reserved for further, or postgraduate courses.

Postgraduate Courses.—Officers not above the rank of lieutenant who make a specialty of marine engineering join an engineering class with headquarters at Annapolis. The course includes design of engines, shop practice and management at private establishments, experimental engineering, and mechanical appliances. The chief engineers of the larger ships are usually selected from officers who have taken this course. A further course in electricity is also to be established for officers. The ordnance specialists also have a postgraduate course. A class of young officers is made up annually to go more thoroughly into such matters as gun design, interior and exterior ballistics, the chemistry of explosives, metallurgy, torpedoes, experimental work, shop practice. Officers selected for the Construction Corps, from Naval Academy graduates

who have had a short sea experience, go first to the Massachusetts Institute of Technology at Boston for a course in naval architecture and kindred subjects, on completion of which they are commissioned assistant naval constructors. A law course is followed by officers detailed for duty in the office of the Judge Advocate General, unless they have previously taken such a course. Foreign languages are studied by young officers detailed as attachés, assistants to the naval attaché, at the embassies and legations in various foreign countries. Assistant surgeons on first appointment follow a course in the Naval Medical School. This insures uniformity of instruction and enables the young medical officers to learn something of naval practice. Assistant paymasters have a short course of instruction in the Bureau of Supplies and Accounts and in the Treasury Department. Officers selected for the Civil Engineer Corps follow a course at the Rensselaer Polytechnic Institute, Troy, N.Y. The work is kept up later by a correspondence course directed by the Bureau of Yards and Docks. Young marine officers follow a course in military practice and duties at the Marine School of Application at Norfolk, Va.

An examination of these courses will show that all the technical work of the navy resulting in the finished ship and her equipment is performed by graduates of the Naval Academy. All the officers concerned in this work are line officers except the naval constructors. Until 1899 the engineer officers belonged to a separate corps, but at that time they were merged with the line.

A principle that has been gaining strength recently is that all combatant officers should belong to one corps and that all technical work in connection with the finished ship should be performed by specialist officers of this one corps. Line officers at present are responsible for all design and work in connection with machinery, ordnance, electricity, torpedoes, wireless telegraphy. The principle stated would require them to take up construction work also, and it would also involve the merging of the pay corps into the line. The surgeons and chaplains are non-combatants under the conventions of international law and would retain their present status. The principle has given excellent results with reference to ordnance, engineering, torpedo, and electrical work, and it is logical to carry it to its conclusion. It is of course not intended that each line officer should take up all specialties, but that specialization should occur in the line instead of in separate corps, and that all line officers should take up at least one specialty.

Naval War College. — A school of a different scope from any of the above is the Naval War College at Newport, R.I. This school was established in the early eighties mainly through the efforts of Rear Admiral Stephen B. Luce.

Its purpose was to afford an opportunity to officers of mature years to study the art of war. It was the first war college proper for naval officers to be established by any nation. Since that time all the leading nations have established similar colleges. Rear Admiral Mahan was one of the early lecturers. His works, delivered first as lectures, have made him and the college famous, and have in effect crystallized the art of naval warfare. The course comprises lectures on naval history, tactics, strategy, logistics, international law, and includes so-called war games, which are exercises in tactics and strategy. The tactical game is played on a table divided into squares to scale. Small ships of lead arranged in divisions, squadrons, and fleets are maneuvered as in action, one move on either side representing a certain number of minutes at a known speed. The effect of gun fire is estimated according to range and the strength of the ships in offense and defense, and is counted up for each move. Torpedo fire is estimated in a similar manner. Each ship has a life of so many units, and is disabled or destroyed according to the units scored against her. The strategical game is played with the aid of charts. Each side has a separate room or rooms, and the umpire another room. Each move represents a certain interval of time and is communicated to the umpire, who in turn informs the opponent of so much as he would be supposed to see for himself in actual maneuvers.

The course consists of a summer conference of officers of all ranks lasting for four months. There is also a so-called long course, made up of selected officers of the conference, which continues on through the winter and the following summer conference, or sixteen months in all. The permanent staff of the college consists of a president, a director, a secretary, and officers for the different departments. Their usual term is three years.

Information was formerly imparted largely through the common efforts of the conference, with a discussion of all subjects that came up in connection with the assigned problems. This method of work was more congenial to the older officers than would have been instruction in classes, such as is usual in schools. Another reason was that at the start the instructors were not much farther advanced than the students. But the development has now reached a point where it saves time to give regular instruction in methods and principles that have found general acceptance.

The War College is more than a school of instruction in the science of war, that is, in a knowledge of principles; it also imparts something of the art, which may be defined as the aptitude of experience. Naturally there can be no experience of actual war gained at the college, but the tactical and strategical exercises are of such a character that the

student must reach a decision and must act on his decision, which is, of course, the essence of experience, in war as in other occupations.

The War College also makes theoretical studies of war plans, not as a part of its work of instruction, but because the lines are parallel. The situations that are brought up for exercise need often only the attaching of names and dates to convert them into plans of campaign. This work is assigned to the War College, not because it is directly connected with the instruction of officers, but because the permanent staff of the college gains familiarity with the conditions involved while in the performance of their regular duties. This work thus becomes of mutual benefit to the college and to the division of operations of the Navy Department.

The War College is thus the culmination of education in the navy. Seamen apprentices and midshipmen have to be trained to give them a start in their career. Enlisted men and officers have to pursue further courses in special technical matters; but the art of war itself, without a knowledge of which all the rest would be energy misapplied, is reserved for the mature deliberations of the War College, which is therefore one of the most important institutions of the navy.

England. — Enlisted Men. — The Royal Navy is recruited from boys (sixteen or seventeen), youths (seventeen or eighteen), men (eighteen to twenty-three), all of whom bind themselves for twelve years, in the fleet or in the reserves. The boys and youths who are not found suitable are discharged, whereas the men (eighteen to twenty-three) serve only a part of the time in the fleet, with exceptions, then go to the reserves. The men of long service who reëngage become entitled to a pension in time, whereas the men discharged early or transferred to the reserves are not so pensioned. The pensions, therefore, are accepted as the cost of good men, while the government saves on those who are discharged early. The reserve men are paid an annual retainer and continue to reëngage up to the age of forty-five to fifty.

Boys on entry are given an elementary course of several months in gunnery, seamanship, and mechanical work. There are several training stations, the principal one being at Shotley, in Suffolk. After leaving the station they go to sea in a cruiser and keep up their work in the same subjects, to which is added a course of stokehold training. This work may occupy a year in all, when the boy is drafted to a sea-going ship. At the age of eighteen he becomes an ordinary seaman. Thereafter he continues his training in the above subjects, with torpedoes and field training added, and he must qualify in all of them before becoming an able seaman. The training of the youths (seventeen or eighteen) is similar to that of the boys, except that the time is shorter. The subsequent career is the same in either case.

Special Schools. — There are special gunnery and torpedo schools for enlisted men at the principal home ports. Of these, Whale Island at Portsmouth is the typical gunnery school, and the *Vernon*, likewise at Portsmouth, the typical torpedo school. The men are trained for the respective rates of seaman gunner and seaman torpedo man. The course is largely practical, designed to give the men a complete working knowledge of the weapons and their mechanisms, ammunition, the methods of target practice, and kindred subjects. A qualifying examination is required before passing. Signal schools for officers and men exist at the principal home ports, where is taught all manner of signaling, including wireless telegraphy.

Physical training has taken a prominent part in the British service of late years. In the days of masts and sails no further training was required other than that necessary in the handling of the ship. Sailing training ships were retained probably longer than their usefulness warranted, almost entirely from the advantages they offered in this direction. "No amount of dexterity on the main royal yard would make a seaman a good gunner or torpedo man, although the physical exercise which the old sailing ships offered was undoubtedly beneficial; but as physical exercise can be introduced in other more useful ways, and in a more scientific manner, it was needless to adhere to it in this form." (From *Parliamentary Return, Admiralty Policy*, 1905, p. 19.) This quotation is an apt summing up of the whole situation as regards sailing training ships, a question that has vexed the navies of other nations as well.

The present physical training is largely on the Swedish system. The gymnastic instructors of the fleet are required to go through a special course at a school on shore—the principal one is at Portsmouth—and the naval regulations require sufficient time to be devoted to the exercises in every ship of the fleet.

The engine-room personnel also have their training schools, one at Devonport, for stokers, who after a two years' course become mechanicians, and may eventually become warrant officers. Another school is that for boy-artificers, with branches at different dockyards. They enter at fifteen or sixteen and are four years or more under training. In the first half of the course the subjects are: practical mathematics, English, elementary science, heat. In the second half they are: applied mechanics, workshop appliances, electricity, marine engines and boilers, mechanical drawing. On completion of the course these boys become engine-room artificers, and may eventually become warrant officers.

Officers. — The method of entry of midshipmen in the early days is known to every reader of Marryat's novels. The first regular school was the Naval Academy at Portsmouth, which was established about 1730, and edu-

cated a limited number of midshipmen, the rest entering the service directly. The age of entry was eleven to fifteen and the length of the course was about three years, after which the pupils went to sea as midshipmen. In 1806 the institution was enlarged and the title changed to Naval College. The number of students was about 100, which still did not include all entries. The course was two to three years. A few lieutenants on half-pay were also in attendance. The college continued as such until 1837, when it was discontinued. Thereafter for twenty years all midshipmen entered the service directly, as in the old days.

The next school for midshipmen, or naval cadets, as they were now called, was established aboard the *Illustrious* at Portsmouth in 1857, and was transferred to the *Britannia* in 1859. Captain Robert Harris was the first head. Under the new plan all candidates for midshipman passed through the *Britannia*, entering between twelve and fourteen and remaining a year. The ages have since been increased and the course has been lengthened to two years. The *Britannia* was moved to Portland in 1862 and to Dartmouth in 1863, where it has since remained. The *Britannia* provided only for the entry of executive officers, what Americans call line officers. The other branches, that is, engineers, surgeons, chaplains, paymasters, marines, entered under separate rules and at various ages.

In 1903 there was put in effect a system for the common entry and training of executives, engineers, and marines. By the new regulations the old system of nominations and competitive entrance examinations was replaced by an interview before an interview committee and a qualifying examination, thus doing away to some extent with the old "crammer." Cadets now enter between twelve and thirteen, spend two years at the Naval College at Osborne, then two years at the Naval College at Dartmouth, and six months in a cruiser, after which they become midshipmen. The midshipmen keep up their studies for three years longer in the regular service and then become sublieutenants. About two years are spent in this rank, after which the officer is promoted to lieutenant.

The instruction of the naval cadets during their course on shore and on board ship includes mathematics, geometrical drawing, physics and chemistry, mechanics, applied mechanics, applied electricity, engineering, mechanical drawing, seamanship, gunnery, navigation, French, German, English grammar and composition, English literature, history, naval history, geography, Bible study, drills, physical training. The course in all the technical branches is both theoretical and practical, with laboratory and shop work, and practice in steam and motor craft.

The midshipmen at sea devote their time

to purely professional and practical subjects, in which they are instructed by the ship's officers. The subjects include: officers' duties, seamanship, gunnery, torpedoes, navigation, pilotage, engineering, about one third of the whole time being given to the last-named subject. The sublieutenants continue the same general subjects, certain of them being selected for a further six months' course at the Royal Naval College at Greenwich (mentioned later), and all perform a stipulated sea service.

On reaching the rank of lieutenant, at twenty-two or twenty-three, officers continue executive (line) duties or, after a total of one year of watch duty at sea, take up one or another specialty, all of which require additional courses, varying in length according to the subject. The symbols (G), (T), (N), (E), (M) before an officer's name indicate that he has qualified as a specialist in gunnery, torpedoes, navigation, engineering, and military duties, respectively. It is the intention that this specialization shall not be permanent, with possible exceptions, but that officers shall keep up their knowledge of line duties and eventually return to the line.

The Royal Naval College at Greenwich is an advanced post-graduate school where officers of the lower ranks are sent to complete certain required courses, and where officers of all ranks may pursue particular lines of study. Assistant naval constructors here receive their education, which extends over a number of years and is specially thorough. The courses at the college in general are professional, technical, and mathematical, and mainly theoretical.

The Royal Naval War College at Portsmouth was established about 1905. The course is for flag officers, captains, and commanders. It consists of playing the tactical and strategic war games, the solution of problems arising out of the strategic conditions of the present day, lectures on naval history, naval architecture, steam, international law, the law of evidence, wireless telegraphy, coast defense. Army and marine officers may attend these courses.

The most noticeable conclusion on studying American and English naval education is the growing opinion in both countries that the education of all combatant officers should be in common, that they should all belong to one corps, and that specialization should take place as necessary in the corps, instead of in separate corps. The Americans took the lead in this direction and have gone further at present than the English, but there are many evidences that the same practice will eventually be reached in both countries.

France.—*Enlisted Men.*—The European countries in general have the conscription system, which simplifies all matters of entry and education. The greater part of the French bluejackets come from the maritime inscrip-

tion, the rest voluntarily from the general conscription. The men from the maritime inscription may enter as young as eighteen. They are sailors by trade and do not need the same training as the conscripts. The latter come in as young as twenty. The special ratings are practically the same as in other services, and all have their special schools, located in the principal naval ports, where the courses average six months. These are naturally preliminary courses only for the lower ratings. Instruction for the higher ratings goes on continually in active service.

Officers.—The French Naval Academy is at Brest. It used to be on board the *Borda*, which was to the French midshipman what the *Britannia* was to his English confrère. Appointments are usually by competitive examination of boys sixteen to nineteen years of age. The course at the school is two years, when the scholar becomes a midshipman second class and goes aboard a school ship for a year, after which he becomes a midshipman first class and joins the regular service.

The subjects taught include the French, English, and German languages, naval history, geography, mathematics, mechanics, physics, electricity, astronomy, navigation, naval architecture, steam machinery, seamanship, ordnance, infantry and artillery, torpedoes. The time devoted to ordnance and engineering has lately been increased.

Besides the Naval Academy, there are special schools at the naval ports for ordnance officers, torpedo officers, infantry instruction, besides service with the board on ordnance. The courses are of various length, after which the officer takes a qualifying examination.

The Superior School of the Navy is at Paris, and is open to lieutenants. The courses are on professional subjects, including tactics and strategy, though the school has little in common with the American and English war colleges. The graduates are placed on a special list, one of the objects being to furnish officers for the staffs of flag officers.

The French have been through the same discussions as other nations as to the unsatisfactory results of having permanently separate corps of officers aboard ship and at the dockyards. The idea of the common entry and training of officers is making headway, but the stumbling block at present seems to be the absorption of the engineers, about two thirds of whom come from below decks, that is, the ranks. There will not be the same difficulty with the other branches.

Germany.—*Enlisted Men.*—Conscription is here in full effect, and, theoretically, whatever training is the best is the one to be adopted. Many boys volunteer for the navy before the age of military service. The intention is to train these boys for the seamen, petty officers, and warrant officers of the fleet. The age of entry is fifteen to eighteen, and they bind them-

selves to serve to the age of twenty-eight. They are assembled on shore and receive some preliminary instruction, but the greater part of their work is in the practice ships, which are used also for training cadets. After about two years the boys are rated seamen. Training now begins in the various specialties, or, for the men with no specialties, with service in the fleet. Conscripts begin their training with infantry drill and later are sent to general service. All conscripts with seafaring knowledge are required to perform their service in the navy.

Gunnery, torpedoes, engineering, and other specialties are taught in separate schools in which the instruction is very thorough. The petty and warrant officers come principally from the men who enter as boys.

Officers.—Cadets enter before the age of eighteen, receive a short military training on shore, and then go to sea for a year in one of the practice ships (used also, as has been seen, for the apprentices). This cruise is followed by a year at the Naval School, formerly at Kiel, now at Flensburg-Mürwick. Then follow courses in ordnance, torpedoes, and military duties, after which comes a final year in the fleet, making four years in all. The principal postgraduate courses for officers are in torpedoes and gunnery. An examination of the various courses for cadets and line officers would indicate that the Germans do not attach as much importance to theoretical subjects as some other nations, but they encourage initiative and insist that officers shall be practical and shall be able to handle the ships and the mechanisms. The courses for warrant officers are thorough and practical, producing men in these grades who by training and experience are noticeably competent.

The seagoing engineers are of a separate corps, with suitable training, as are the surgeons and paymasters. There are also a nonseagoing machinery construction corps and a naval construction corps. Both of these are civil corps. The subject of common entry and training for all combatant branches has been discussed in Germany, but has not made much headway.

Other Countries.—The principles of education that appear in the navies of the United States, England, France, and Germany are found also in one form or another in all navies. A cosmopolitan influence is always at work in these organizations, owing to their foreign cruises and the knowledge they thus obtain of each other. The effect is noticeable in many ways, from their uniforms, which are all much alike, to their education and training, which are always tending in the same direction, though some nations lead and others follow. NEAL, EDWARD DUFFIELD (1823-1893) — Educational writer; was graduated at Amherst College in 1842, and later studied theology at the seminary at Andover. He engaged in the ministry of the Presbyterian Church, and was active in the organization of the first public school at St. Paul. He was the first territorial superintendent of public instruction of Minnesota (1851-1858), and he was chancellor of the University of Minnesota from 1858 to 1861. He was one of the secretaries of President Lincoln during the Civil War, and from 1873 to 1884 he was president of Macalister College at St. Paul, which he had helped to found. He was the author of a number of historical works and several monographs on the history of American education.

W. S. M.

NEANDER (NEUMANN), MICHAEL (1525-1595). — One of the most famous teachers in Germany, regarded as second to Melancthon (*q.v.*). He was born at Sorau and studied at Wittenberg, taking lectures with Luther and Melancthon. In 1545 he became assistant, then corrector, at Nordhausen, and in 1550 went to the cloister school at Ilfeld, where he became rector in 1559 and was active for forty-five years. Neander is a typical representative of the best educational ideals of the Renaissance-Reformation period. His first task at his school was to produce order out of chaos, and he then applied himself to reforming the curriculum. Dissatisfied with the prevailing curriculum, which devoted most of the pupils' time to a dry study of grammar and left them ignorant in the end, he set before himself the task of inculcating a feeling of reverence for God and a knowledge of letters, languages, arts, physics, history, geography, ethics, and the principles of medicine. He claimed that he could teach in half a year more than other schools taught

in two years. His grammars and textbooks covered all the subjects which he attempted to teach. He published thirty-nine books during his lifetime and left fourteen others in manuscript. His educational aims and practice are formulated in a pamphlet, published in 1590: *Bedenken an einen Guten Herren und Freund. Wie ein Knabe zu leiten und zu unterweisen, dass er ohne grosses Jagen, Treiben, und Eilen mit Lust und Liebe vom 6. Jahr seines Alters bis auf das 18. wohl und fertig lernen möge Pictalem, Linguam Latinam, Graecam, Hebraeam, Artes und endlich Philosophiam* (*Thoughts to a Gentleman and Friend How to direct and instruct a Boy so that he may without much Hurrying, Pressure, and Haste learn well and readily with Pleasure and Love, from his sixth year to his eighteenth, Latin, Greek, Hebrew, the Arts, and finally Philosophy*).

NEARSIGHTEDNESS. — See EYE.

NEBRASKA, STATE OF. — Originally organized as a territory by the Kansas-Nebraska Act of 1854, and admitted as the thirty-seventh state in 1867. It is located in the western half of the North-Central division, and has a land area of 76,808 square miles. In size it is one fourth larger than the six New England states, and nearly as large as England, Scotland, and Wales combined. For administrative purposes the state is divided into ninety-two counties, and these in turn into over seven thousand school districts. In 1910 Nebraska had a total population of 1,192,214, and a density of population of 15.5 per square mile.

Educational History. — The first school law was enacted and the first school opened in 1855. The State Librarian was made *ex officio* State Superintendent of Public Instruction, and each county was directed to elect a county superintendent, who was to establish school districts, examine teachers, and look after the interests of the schools. A district school tax, the rate bill, and a county school tax of three mills were provided for. Few schools were organized under this law. Three colleges were chartered by the first legislature, only one of which was ever organized. The report of the *ex officio* State Superintendent to the legislature in 1857 showed that there were four county superintendents, seventeen school districts, and six schools in operation in the state. In 1858 a new school law, based on that of Iowa, and with the township instead of the school district as the unit, was adopted in place of the law of 1855. The county superintendency was abolished, and a territorial school commission was created. The law was cumbersome, unsuited to the needs of the time, and

education made but little progress under it. By 1860 but twenty-nine schools were reported to be in operation. In 1861 the office of the Territorial Commission was in turn abolished, and the Territorial Auditor was made *ex officio* School Commissioner. In 1866 a school was organized at Peru, which in 1867 was deeded to the state for a state normal school.

The new constitution of 1867, adopted on the admission of the state, contained but little mention of education. The legislature was directed to provide for "an efficient system of common schools throughout the state," and the use of public school funds for secondary schools, or the sale of school or university lands for less than \$5 per acre, was forbidden. The first legislature of the new state, acting partly in response to the demands of the first state convention of educators, adopted a new school law, which went into force in 1869. The district system of school administration was reestablished, and this has remained to the present time. The office of the State Superintendent of Public Instruction was created, and county superintendents were provided for. The State Superintendent was directed to examine teachers, recommend textbooks, and apportion the school funds to the counties on the school census basis. Within the counties the present form of distribution was provided for. Township high schools were permitted in 1858, but few, if any, were organized. From 1867 to 1873 a few high schools were organized by special legislative acts, and in 1873 the first general high school law was enacted. The University of Nebraska was chartered and began instruction in 1869.

In 1875 a new constitution, which is still in force, was adopted by the people. This made much more detailed provision for education than had the earlier one of 1867. Except for a few minor amendments, these provisions have since remained. A State Board of Commissioners for the control of the school lands and school funds was created; a minimum sale price of \$7 per acre was fixed for all educational lands; the school funds were defined, the sources for increase were enumerated, the use of the income specified, and all educational funds were declared to be trust funds, to remain forever inviolate and undiminished; the legislature was directed to provide for the free instruction of all persons five to twenty-one years of age; reformatory and parental schools were permitted; and the government of the University of Nebraska was provided for. No important changes in the school laws followed, and almost no legislation of importance took place during the next fifteen years.

Beginning in 1891, a series of important acts were adopted, which have materially improved the educational conditions of the state. In 1891 the free textbook law was passed. In 1893 a new law provided for the permissive attendance of pupils at some other school than that of

their district, under certain conditions, and this was extended in 1895 to include transportation across county lines. In 1895 the first of a series of laws was enacted having for its purpose the provision of free high school education to all children in the state, and this was followed in 1899, and again in 1901, by other laws of similar intent, though all three were declared unconstitutional by the courts. Finally, in 1907, a law was enacted which has stood. In 1897 a transportation law was enacted, and the certification of graduates of the University of Nebraska on credentials was provided for. In 1889 a compulsory education law and a child labor law were enacted, under the provisions of which education was made compulsory and labor of certain kinds was forbidden for children between the ages of seven and fourteen years. These laws were amended in 1907 to increase the age in all cities to sixteen years. In 1901 attendance at teachers' institutes was made compulsory; elementary agriculture was made a required subject in the teachers' examinations for a first-grade county certificate; the number of third-grade county teachers' certificates allowed to any one person was reduced from three to two; and a union rural high school law was enacted. In 1903 an additional state normal school was provided for; Junior Normal Schools were created; and the giving or sale of cigars, cigarettes, or cigarette paper to any one under eighteen years of age was forbidden. In 1905 the certification law was revised, and a partial state system of examination and certification was provided for. Questions were to be prepared and all answer papers graded by the state office, and all teachers in high schools were required, after 1907, to be graduates of a university, college, or advanced course of a Nebraska normal school, or to hold a professional state certificate. In 1907 a number of important laws were enacted. A free high school law was passed for the fourth time; county high schools were provided for; normal training in the high schools of the state was authorized, \$50,000 of state aid appropriated for such, and a state examination and approval of all such schools required; \$50,000 was appropriated from the state treasury to enable all school districts in the state to provide a seven months school (raised in 1909 to \$75,000 and the minimum term reduced to five months); the state school tax, previously levied, was repealed; the number of Junior Normal Schools was increased from five to eight, and the summer term of such reduced from ten weeks to six or eight weeks; school district libraries were created; and the compulsory education law was extended from fourteen to sixteen years for the cities of the state. A number of minor changes and revisions in the laws were made in 1909 and 1911. In 1911 the minimum salaries of county superintendents were fixed and very materially increased; new standards for city certification

were created; and a state fire day, to give instruction and drill in combating fires, was provided for.

Present School System. — At the head of the present state school of Nebraska is a State Superintendent of Public Instruction, elected by the people for four-year terms, and receiving a salary of \$1800 a year. His duties are to visit the schools; to decide all disputed points in the school law, his decisions being binding until overruled by the courts; to prescribe forms for all blanks and reports; to publish the school laws; to outline a state course of study for the schools; to prepare all questions for the examination of teachers, and to oversee the grading of all examination papers; to make rules and regulations for the guidance of county superintendents; to apportion the state school funds; to organize teachers' normal institutes (Junior Normal Schools) when and where deemed desirable, to provide the instructors for them, and to outline the instruction; to designate high schools in which normal instruction may be given, to outline the course, and to inspect and approve the schools; and to make an annual report to the governor. He also serves, *ex officio*, as a member of the Board of Control for the state normal schools, and as a member of the State Library Commission.

For each county there is a county superintendent of schools, elected by the people, for two-year terms. To be eligible for the office the candidate must hold a first-grade county teacher's certificate in all counties having a population of over 1000 inhabitants, and his salary, as determined by law, cannot be less than from \$1000 to \$2200, according to the size of his county. It is his duty to visit each school in his county annually; to hold each summer a teachers' institute of one week duration; to forward all blanks and the state course of study to trustees and to teachers, and to examine and correct their reports when made to him; to change the boundaries of the school districts, and to transfer individual children; to adjudicate district disputes; to act, in general, subject to the instructions of the State Superintendent; to act for the state in holding examinations of teachers, and in issuing certificates to those who pass the examinations; to act as one of the Board of Regents for any county high school formed in his county, and as one of the board of district trustees for any school district in his county having less than three voters in the district; to certify to the State Superintendent the number of districts in his county entitled to state aid to enable them to maintain a five-months school; to assist in the enforcement of the compulsory education law; and to make an annual report to the State Superintendent.

Each county is divided into a number of school districts, there being about 7000 in the state, each of which is a body corporate. For

each of these the people elect, in annual school meeting, a board of three district school trustees, electing them specifically as moderator, treasurer, and director. The moderator presides at all district board meetings; the treasurer has the custody of all district funds; and the director, or clerk, transacts most of the business for the district. The director has general charge of the schoolhouses and grounds; draws all orders on the district funds; takes the annual school census; may hire the teacher, under direction, and sign contracts; prepares an estimate of needs for the annual district meeting; and presents an annual report to the county superintendent. The district boards have general care of the schools; grade and classify them to fit the course of study as outlined; adopt and furnish free all textbooks, and may sell the same at cost to any pupil; may admit nonresidents, and expel pupils; may, by a two-thirds vote, contract with another school district or with a high school district to educate part, or all, of their pupils, and may provide transportation for part or all of the pupils. The annual district meeting, held in June of each year, votes the annual district tax; may vote a tax for a schoolhouse fund; determines the length of the school term, if any, beyond the minimum set by law; and determines all questions relating to selecting the school site or moving the schoolhouse. All residents of the district, owning property or having children, aliens and women included, may vote at these district meetings. The county superintendent, on petition of one third of the voters, may change the boundaries of a district, and on petition of one half may divide a district or consolidate two or more districts, except that no new district may be formed if it contains less than four sections of land or unless its valuation exceeds \$15,000. Any district having 150 children of school census age (five to twenty-one) may elect a board of six trustees, who then designate their own officers, grade and classify the schools, may establish a high school, may prescribe the course of study and textbooks for the schools, and have general supervision of the schools. They present a report and estimate to the annual district meeting, which then votes the amounts required. Cities having 1500 or more inhabitants may be erected into separate city school districts, with similar powers.

Secondary Education. — In addition to the above, for districts having more than 150 school census children, any two or more rural districts may vote to unite to form a union rural high school, which is then supported by the districts so uniting in proportion to their assessed valuation. Any county may also vote to establish a free county high school, which is under the charge of a board of regents, consisting of the county superintendent of schools, the county treasurer, and three trustees elected by the district school directors of the county.

This board employs all teachers; estimates the amount needed each year, up to five mills, and certifies the same to the county commissioners for levy; and has the usual district powers for organization and control. The school must have five acres of land, and must teach manual training, domestic science, and agriculture in the ninth and tenth grades, and agriculture and normal training in the eleventh and twelfth grades. Diplomas of graduation are valid for teaching in the county for three years.

The free high school law also makes provision for four years of free high school education for all children in the state. Any pupil holding a certificate of graduation from the eighth grade may be admitted, on application of his parents to the county superintendent of schools, to any high school, if there is room. The district receiving such pupils receives seventy-five cents per week per pupil from the free high school fund of the district from which the pupil comes. This is an added tax and must be levied for the purpose, unless such district is unable to provide a nine-months elementary school. The schools follow courses of study made out by the State Superintendent of Public Instruction and the University of Nebraska.

Teachers and Training.—The system of certification for teachers is a state system in process of evolution. Both state and county forms of certificates are issued, but the questions for the county examinations are now prepared and the answers read and graded in the State Superintendent's office. The county superintendent still issues the certificates, but on the basis of grades reported to him from the state office, and the county certificates are valid, at the discretion of the county superintendent, for a variable period. Within recent years there has been a marked extension of the principle of granting teachers' certificates on the basis of credentials from educational institutions, until now the provisions for this are very liberal. The state also has made a commendable beginning in the interstate recognition of credentials. To teach in a high school, the teacher must hold a first-grade county certificate, or be a graduate of a normal school, college, or university. Fees are charged for all teachers' examinations and registering of certificates, to pay for the expense of grading papers, and to provide a teachers' institute fund.

For the training of future teachers the state maintains three state normal schools, at Kearney, Wayne, and Peru. These are large schools. The state also maintains eight so-called "Junior Normal Schools," located in eight cities in different parts of the state. These hold sessions of six to eight weeks during the summer months, enroll from 100 to 250 students, and one week of the session constitutes the summer institute of the county where held. The public school buildings and apparatus are used

for the sessions, the instructors are appointed by the State Superintendent, and the course of instruction is that of the elementary course of the state normal schools, in which proportionate credit is given for the work done in these summer schools.

For the training of teachers for the rural schools the state grants \$350 per year to all high schools providing normal instruction in the eleventh and twelfth grades, when approved by the State Superintendent. Graduates of these schools receive a second-grade county certificate, and the number of such schools and graduates is increasing rapidly. In 1908, 65 approved high schools graduated 550 teachers; in 1909, 98 schools graduated 763 teachers; in 1910, 109 schools graduated 894; and in 1911, 112 schools graduated approximately 1025. These schools are rapidly raising the standard of efficiency of the rural schools of the state.

School Support.—Nebraska originally received the 16th and 36th sections for schools, on its admission to the Union, a total of 2,702,044 acres. The 500,000 acres of land granted to new states for internal improvements, and the 5 per cent from the sale of government lands within the state, were also added to the school fund. About one half of this grant has been sold, and almost all of the remainder is under lease. The present fund stands at about seven millions, and the probable future of the fund is about twenty-five millions. The interest on this fund is apportioned to the counties on the sole basis of census, and from the counties to the districts, one fourth equally to all districts and three fourths on census. Almost the entire support of the schools of Nebraska comes from local taxation, which may go as high as 25 mills in districts and 3.5 mills in cities, but with the proviso that in districts having four children or less the total tax must not exceed \$400, and in districts of five to sixteen children it must not exceed \$50 per child. Additional taxation, up to 10 mills, may be levied for a schoolhouse building fund. In all districts levying the maximum tax, the state will grant additional aid to enable them to maintain a five-months school, provided the total annual expense does not exceed \$275. For this purpose the state now appropriates \$75,000, and a similar sum is appropriated for normal training in high schools. These sums are regarded as in part compensating for the state school tax of one half cent, withdrawn in 1907. Fines and liquor licenses go to the local government unit imposing them.

Educational Conditions.—The state is essentially a rural and an agricultural state. There are few large cities, and three fourths of the people live in the rural districts; 99 per cent are white, and about 85 per cent native born. The illiteracy in 1900 was the lowest (2.3 per cent) in the Union. The conditions for education are good. The state has recently become deeply interested in the

NEBRASKA, STATE OF

teaching of agriculture and domestic science, and these subjects, begun in 1905, are being rapidly introduced into the schools. Boys' and girls' clubs have been formed in many places, the enrollment in 1910 being over 32,000. High schools have experienced a rapid development within the past decade, and the training of teachers has made rapid progress. School libraries have recently been provided for, and ten cents per pupil may be set apart each year for a library fund. A state library commission of five suggests books for purchase.

The state has a fairly good compulsory education law, which all districts must enforce. There is also a reasonably good child labor law. Children seven to fifteen, in all districts, must go to school at least two thirds of the school term, and not less than twelve weeks each year, and, in cities, children seven to sixteen must go to school all the time the schools are in session. Deaf children, seven to eighteen, must attend the state school. Exemptions are granted for good reasons; attendance at parochial or private schools may be accepted; the school may appoint physicians to examine as to health and disabilities; and children fourteen to sixteen may work, if attending evening schools. All cities must appoint truant officers, and may provide truant schools. All other districts must enforce the law, and may call upon the county superintendent to assist. The school census, when taken, must be taken with a view to assisting in the enforcement of the compulsory education law. All children of paupers in county poorhouses must be sent to school at the expense of the county.

Higher and Special Education.—The University of Nebraska, a large and rapidly growing institution (*q.v.*), in Lincoln, stands as the culmination of the public school system of the state. This institution includes both the university proper and the Agricultural and Mechanical College, though the legislature of 1911 voted to establish another agricultural college in the western part of the state. Besides the state university, the following institutions of higher learning exist within the state, all being open to both sexes:—

NAME	LOCATION	OPENED	CONTROL
Doane College . . .	Croft	1872	Congr.
Hastings College . .	Hastings	1882	Presby.
Bellevue College . .	Bellevue	1883	Presby.
Nebraska Wesleyan University . . .	University Place	1888	M. E.
Cotner University . .	Bothany	1889	Chr.
York College . . .	York	1890	U. B.
Union College . . .	College View	1891	7th D. Adv.
Grand Island College	Grand Island	1892	Bapt.

The state maintains, as special institutions, the Girls' Industrial School at Geneva; the Nebraska State Industrial School for Boys at Kearney; the Nebraska Industrial Home at

NEBRASKA, UNIVERSITY OF

Milford; the Nebraska Institution for the Blind at Nebraska City; the Nebraska School for the Deaf at Omaha; and the State Institution for Feeble-minded Youth at Beatrice.

NEBRASKA, UNIVERSITY OF, LINCOLN, NEB.—A state institution established by act of legislature in 1869. It consists of five colleges (graduate, arts and sciences, teachers', engineering, law) and two schools (pharmacy and practice high school), situated on a six-block campus only three blocks distant from the business center of the capital city of Lincoln, a college of agriculture and a school of agriculture located on a 320-acre campus two miles and a half east of the city campus; a college of medicine located in the state's metropolis of Omaha, and a second school of agriculture recently located at Curtis, in the western portion of the state. In addition, the university is affiliated with the Lincoln Dental College, and several of the departmental experts of the university have been made *ex officio* specialists in the general employ of the state. The university also has supervision over experiment stations at Lincoln, North Platte, Valentine, Scotts Bluff, and Culbertson.

The university has its general outline prescribed by the state constitution, and the details of its organization determined by various acts of the state legislature. Administrative control centers in an elected board of six regents and a chancellor chosen by the board of regents, but the development of educational policies within the university is largely left in the hands of a senate consisting of heads of departments and the deans and faculties of the various colleges.

The chief source of revenue for maintenance of the university is a legislative tax of one mill upon the grand assessment roll of the state. Additional revenues are derived from lease and sale of lands granted to the state by the federal government, from federal money grants under the congressional acts of 1887, 1890, and 1906, from interest on permanent fund investments, and from various small fees paid by students.

In 1912 the equipment of the institution consisted of nearly thirty buildings of various sizes, the instructional staff numbered over three hundred, the student registration totalled 3657, the number of graduates for the year was 375, and the alumni roster showed an accumulation of over 5000 names. The entrance requirements are fifteen units of high school work. The usual university degrees are conferred on the completion of the appropriate courses.

C. E. P.

NEBRASKA WESLEYAN UNIVERSITY, UNIVERSITY PLACE, NEB.—An institution under the control of the Methodist Episcopal Church, organized in 1887 by a union of the denominational institutions founded earlier at York, Bartley, and Central City. In place of these struggling institutions there now exists one vigorous university having, in 1912, an enrollment of nearly 1000. The campus consists of forty-four acres, including an athletic park. The main buildings are four in number. The total equipment is valued at \$350,000. The productive endowment is \$350,000.

The departments are as follows: college of liberal arts, teachers' college, academy, conservatory of music, school of expression and oratory, and school of art. Among these departments, the college of liberal arts has the highest enrollment, numbering three hundred and seventy-three. The faculty consists of forty members.

NECESSITARIANISM.—See DETERMINISM; WILL, FREEDOM OF THE WILL.

NECKER DE SAUSSURE, MME. ADRIENNE ALBERTINE (1765-1841).—French writer. She was married to Jacques Necker, nephew of his more famous namesake of the Revolutionary period, and is known in the educational world largely on account of her *L'éducation progressive, ou étude sur le cours de la vie* (1828-1838), crowned by the Academy (1832). This is one of the most interesting contributions to French educational literature. Like so many similar undertakings,—a work in several volumes whose publication drags out over a period of years,—it is characterized by a lack of unity. The point of view changes several times, although in the end the author pursues her original purpose and confines herself to "the education of women." All her writings are dominated throughout by a strong religious influence. Her work was translated in part into English soon after its appearance by Mrs. Willard and Mrs. Phelps (Boston, 1835), and in 1839 two volumes were translated anonymously in London. F. E. F.

NEEDLEWORK.—See HOUSEHOLD ARTS.

NEEF, JOSEPH (1770-1854).—A colleague of Pestalozzi who established the first Pestalozzian schools in the United States. He was born at Soultz, Alsace, Dec. 6, 1770. He was educated for the priesthood, but gave up the notion of taking orders and entered the army of Napoleon. He was wounded in the

battle of Arcole, Italy, in 1796, and three years later joined Pestalozzi as instructor of gymnastics in the institution which the great Swiss educator was conducting at Burgdorf. In 1803, at the request of Julien and other French apostles of Pestalozzi, Neef was sent to Paris to open a Pestalozzian school. Here three years later he was engaged by William Maclure (q. v.), an American philanthropist, to come to Philadelphia and establish a Pestalozzian school. The school at Philadelphia was in existence for several years, when it was removed to Village Green, Delaware County, Penn. David Glasgow Farragut, subsequently the famous American admiral, was a pupil in the Village Green school. Later Neef moved to Louisville, Ky., where he engaged in educational work. With the establishment of the social colony at New Harmony, Ind., by Robert Owen (q. v.) and William Maclure in 1825, Neef was invited to join the community in the capacity of schoolmaster. When the colony broke up in 1828, he went first to Cincinnati and later to Steubenville, Ohio, where he conducted schools. In 1834 he returned to New Harmony, where he died April 8, 1854. In his educational labors in America, Neef followed in the main the methods of Pestalozzi. He abolished books from the lower classes and gave instruction by oral means; he taught nature and geography by field lessons; music and gymnastics were given important places in his educational scheme, and pupil government administered the necessary discipline. His *Plan and Method of Education*, published at Philadelphia in 1808, was the first strictly pedagogical work in the United States published in the English language. It is a comprehensive survey of the aims and methods of education in a style that is singularly clear and forceful, although written by a foreigner. In 1809 he published an English translation of the logic of Condillac, and in 1813, *Method of instructing Children rationally in the Arts of Reading and Writing*. W. S. M.

NEGATIVE NUMBERS.—Among the artificial numbers (see NUMBER) is a domain of negative numbers. If $2 + x = 0$, x is evidently not a positive integer, and neither can it be a positive number of any kind. It must be such a number as will cancel 2 when added to it, and it is called a negative number. Be-

cause $2 - 2 = 0$, it has come to be the custom to represent x in this case by -2 , where the negative sign is a symbol of quality and not one of operation. Hence we have two meanings for the negative sine, as, indeed, we have for the positive sign.

Negative numbers were slightly recognized by Diophantus (*q.v.*) and the Hindu algebraists (see ALGEBRA), but it was not until Descartes (*q.v.*) had worked out his suggestion for analytic geometry (*q.v.*) that they came to be well understood. Since the seventeenth century they have been generally recognized as valuable adjuncts to work in algebra, although an occasional mathematician (like Frend, the father-in-law of De Morgan) has declined to use them. Their value in physics has now been so fully recognized that they have an added importance in algebra.

The negative number is, at present, generally introduced early in algebra. This was not formerly the case, but so many simple and practical illustrations of these numbers are now known as to make their early use entirely feasible. Among the simple illustrations are north and south latitude, east and west longitude, above and below zero on the thermometer, assets and debts, weight and the upward pull of a balloon, and the "tug of war" in pulling a rope. Pupils in algebra have no difficulty in comprehending the significance of these numbers if they are illustrated in such a manner.

Some effort has been made to use different symbols for the negative as an adjective and the minus sign as indicating subtraction. Thus we have $-a$ for the former and $-a$ for the latter. The effort has not, however, met with much favor in the mathematical world.

A slight effort has also been made by teachers to use the expression "negative a " instead of "minus a " in speaking of the quantity, reserving "minus" for the operation only. This effort has never commanded much attention, although it is a rather harmless distinction for a beginner to make. The fact is that mathematical usage allows "minus a " and does not adapt itself readily to the longer expression "negative a ." D. E. S.

NEGLECTED CHILDREN.—See CHILDHOOD, LEGISLATION FOR THE CONSERVATION AND PROTECTION OF; CRIPPLED CHILDREN, EDUCATION OF; JUVENILE DELINQUENCY; PENOLOGY, EDUCATIONAL ASPECTS OF; REFORMATORY EDUCATION.

NEGRO, EDUCATION OF THE.—The English people who sent out the first colonists were interested in the religious education of the Indians. When the number of slaves increased, they became interested in the education of the negroes, who were then also a "heathen people." The first public school in Virginia, established about 1620, was for the benefit

of these Indians and negroes. This school was destroyed in the Indian war of 1622 and little or nothing was done to educate either of them until the year 1701, when a society was organized in England to carry the gospel to the Indians and the negroes in America. In 1702 Samuel Thomas, the first missionary of the society, stated that he had taken much pains to instruct the negroes and taught twenty of them to read. Elias Neau, a French Protestant, in 1704 established a catechizing school for the Indian and negro slaves in New York, which continued successfully for a number of years.

The Moravians, in 1738, established missions exclusively for negroes. In 1745 the Society for Propagating the Gospel in Foreign Parts (*q.v.*) established a school in Charleston. Its pupils at one time were as many as sixty, and about twenty were sent out annually "well instructed in the English language and the Christian faith." When slavery was introduced into the colony of Georgia in 1747, representatives from twenty-three districts met in Savannah and drew up resolutions in regard to the conduct of masters towards their slaves. It was declared "that the owners of slaves should educate the young and use every possible means of making religious impressions upon the minds of the aged." In 1747 the Presbyterians began the religious instruction of the negroes in Virginia.

In 1750 the Rev. Thomas Bacon, himself a slaveholder, established in Talbot County a mission for poor white and negro children. The Methodist Conference of 1790 raised the question, "What can be done in order to instruct poor children, white and black, to read?" The reply was, "Let us labor as the heart and soul of one man to establish Sunday schools in or near the place of worship. Let persons be appointed by the bishops, elders, deacons or preachers, to teach gratis all that will attend from six in the morning till ten, and from two in the afternoon till six, where it does not interfere with public worship. The council shall compile a proper schoolbook to teach them learning and piety."

There was, however, some opposition to the education of slaves. This opposition grew as slavery became more of a political than an economic institution. In 1740 the colony of South Carolina passed a law imposing a fine of one hundred pounds upon any one who should teach any "slave or slaves in writing in any manner whatsoever." Georgia, in 1770, passed a similar law, which imposed a fine of twenty pounds upon any person teaching a slave to read and write.

Immediately after the Revolutionary War there was a feeling all over the United States that slavery was soon to pass away. The invention of the cotton gin, however, increased the value of slave labor, caused the belief that it was necessary to the economic growth

of the South, and finally this belief to become a conviction that slavery was to be a permanent institution in the Southern states. This change in public opinion was reflected in the laws. Virginia, in 1819, passed an act prohibiting all meetings of slaves, free persons, and mulattoes in the night or in any school or schools for teaching them reading and writing. In 1829 Georgia passed a law forbidding any person of color to receive instruction from any source. In 1830 Louisiana passed a law forbidding free negroes entering the state and persons of color being taught. North Carolina, in 1835, abolished the schools for free persons of color, and enacted a law that no descendants of negro parents to the fourth generation should enjoy the benefits of the public school system. Mississippi and Missouri passed similar laws. In spite of these severe laws, negroes in one way or another managed to receive some education. In New Orleans, Charleston, Savannah, and other places there were clandestine schools attended by the children of free negroes and sometimes of slaves. Schools for free colored people were never abolished in Maryland, Kentucky, Tennessee, Florida, and Texas.

Up to a few years before the Civil War, there was almost as much opposition to negro education in the North as in the South. In 1831, at the First National Convention for Colored People, steps were taken to found a college for colored youth. In the course of the next year three thousand dollars was raised for establishing "a school on the manual labor plan." Several acres of land were bought in New Haven, Conn., for this purpose. The citizens of that city, however, raised a great cry and protested vigorously. At a public meeting presided over by the mayor it was resolved by a vote of seven hundred to four that "the founding of colleges for educating colored people is an unwarrantable and dangerous undertaking to the internal concerns of other states and ought to be discouraged," and that "the mayor, aldermen, common council and freemen will resist the establishment of the proposed college in this state by every lawful means." On the 3d of July, 1835, a town meeting was called in Canaan, N.H., and a committee chosen to remove Noyes Academy because it had enrolled several colored students. About a month later, the committee, aided by three hundred persons and a hundred yoke of oxen, literally carried out the instructions of the town meeting. Because Prudence Crandall, in 1833, at Canterbury, Conn., admitted colored girls to her boarding school, a law was passed making it a crime to open a school for negroes in that state, and she was imprisoned and mobbed. In spite of the opposition to negro education, the number of negro schools, primary and secondary, steadily increased. Of the secondary schools there exist: the Insti-

tute for Colored Youth, Cheyney, Penn.; the Avery Institute, Allegheny City, Penn.; and the Ashum Institute, now Lincoln University, Chester, Penn.

The outbreak of the Civil War increased the negroes' opportunities for education. Almost as soon as any portion of the seceding states was occupied by the Union Army, efforts were begun to give the refugees some schooling. In September, 1861, under the guns of Fortress Monroe, a school was opened for the "contrabands of war." In 1862 a number of similar schools were operated in Virginia, North Carolina, and South Carolina. On Dec. 17, 1862, Colonel John Eaton was ordered by General Grant to assume general supervision of freedmen in the departments of Tennessee and Arkansas. Under him, schools multiplied. In October, 1863, General Banks created commissioners of enrollment, who established the first public schools in Louisiana. March 22, 1864, he created a board of education "for the rudimental instruction of the freedmen." In December of this same year this board reported 95 schools, 162 teachers, and 9571 scholars. Education was also going on in the negro regiments, where thousands of soldiers persuaded their officers to become schoolmasters, and in this way learned to read, write, and cipher.

Congress on March 3, 1865, created the Freedmen's Bureau (*q.v.*). It was authorized to cooperate with benevolent or religious societies in the education of the negro. Numbers of these societies had done good work before the establishment of the bureau, and afterwards continued their work. Some of these organizations were the American Missionary Association, Western Freedmen's Aid Commission, American Baptist Home Mission Society, and the Society of Friends. After the surrender of Vicksburg and the occupation of Natchez, other teachers were sent by the United Presbyterians, Reformed Presbyterians, United Brethren in Christ, Northwestern Freedmen's Aid Commission, and the National Freedmen's Aid Association. Apart from the general government, the American Missionary Association was the chief body that supplied the educational needs of the negro. Up to 1866 the Freewill Baptists, the Wesleyans, the Congregationalists, and Friends in Great Britain sent their aid through the American Missionary Association.

After Appomattox the whole race started to school. The freedmen could not wait for schoolhouses to be built or for teachers to be provided. School was held anywhere and everywhere. The enthusiastic learners got up before day and studied in their cabins by the light of pine knots. They sat up until late at night, drooping over their books trying to master the secrets they contained. By a fire in the woods at night, a dozen or more people of both sexes and of all ages sat about

with books in their hands studying their lessons. Sometimes they would fasten their primers between their plow handles, so that they could read as they plowed. Negro coal miners tried to spell out the words of a little reading book by the dim light of a miner's lamp, hundreds of feet below the earth. In the early days of freedom, public schools were not infrequently organized and taught under a large tree. Some of the early schoolhouses consisted of four pieces of timber driven into the ground and brush spread overhead to keep out the sun and rain. Night schools were very popular; men and women, after a hard day's work in field, shop, or kitchen, would spend two or three hours at night in school. Many got their first lessons in reading and writing in the Sunday schools, which frequently had more spelling books than Bibles. The teacher was likely to be any one who knew something some one else did not know. It sometimes happened that those who could read better than they could write became teachers of reading, and those who could write better than they could read, teachers of writing.

The number of regular schools rapidly increased; white teachers of all classes and both sexes came from the North. There were also numbers of negro men and women who, having escaped from slavery and gained some education in the North, now returned to become teachers of their race. There were also many Southern white people who, being left without occupation directly after the war, were glad to teach the freedmen in order to eke out a livelihood. In 1866 there were 975 schools and 90,778 pupils; the next year there were 1839 schools and 111,442 pupils. Ten years from this time the number of colored children enrolled in public schools of the sixteen former slave states and the District of Columbia was 571,506. In 1908 the number was 1,712,137, and the number of public school teachers was 30,334.

Immediately after the war many schools for higher education were established. In 1865 the Sixty-second and Sixty-fifth United States colored regiments generously contributed from their wages \$6000 to found Lincoln Institute at Jefferson City, Mo. The same year Shaw University was started at Raleigh. Hampton Institute (*q.v.*) was founded in 1866 by General Samuel Chapman Armstrong. Fisk University was established at Atlanta; Biddle University at Charlotte; and Howard University, named after General O. O. Howard, at Washington, D.C. In 1869 Straight University was established at New Orleans; Tougaloo University at Tougaloo, Miss.; Talladega College at Talladega; and Claflin University at Orangeburg, S.C. (*qq.v.*). At present (1912) the United States Commissioner of Education reports 189 institutions devoted to secondary and higher education. No one of these institutions is devoted entirely to collegiate work, but in all

of them are found some students of secondary grade, and in the most of them students of elementary grade. In almost all of these institutions some form of industrial training is given. There were, in 1910, 2941 teachers, and 57,915 students, of whom 23,896 were of elementary grade, 19,654 of secondary grade, 13,124 of collegiate grade, and 2080 professional students; 29,954 of the students were receiving industrial training, 11,943 males and 18,011 females. The Helen B. Cobb Industrial Institute, at Barnesville, Ga.; Ingleside Seminary, Burkessville, Va.; Mary Allen Seminary, Crockett, Tex.; Mary Holmes Seminary, West Point, Miss.; the Hartshorn Memorial College, Richmond, Va.; Scotia Seminary, Concord, N.C.; Spelman Seminary, Atlanta, Ga.; and St. Frances Academy, Baltimore, Md. are devoted exclusively to the training of females. Gammon Theological Seminary, Atlanta, Ga., and Stillman Institute, Tuscaloosa, Ala., are exclusively theological seminaries. Thirteen other institutions have theological departments. Two institutions have departments of dentistry, three of pharmacy, four of law, and seven schools of medicine.

Special funds which have done much for the promotion of negro education are the Peabody Fund (*q.v.*), created in 1867 and 1869, and devoted to the education of whites and blacks in the South; the John F. Slater Fund (*q.v.*), created in 1882 for the purpose of "uplifting the lately emancipated population of the Southern states and their posterity"; the Daniel Hand Fund, created in 1888 to aid the American Missionary Association in its work in the South; and the Anna T. Jeanes Fund (*q.v.*), created in 1907 to aid in the maintenance and assistance of elementary schools for negroes in the South.

When the negro was emancipated, probably not more than 5 per cent of the race could read or write. In 1900, after less than forty years of freedom, 55½ per cent could both read and write. In 1910, 30.5 of the negro population is illiterate. Although the negroes constitute over 11 per cent of the population and still have the largest proportion of ignorance, yet they receive only about 2 per cent of the total amount expended for education. The total yearly income of all negro schools for industrial and higher education is not more than two and a quarter million dollars, which is less than the income of Harvard University in 1908. The yearly expenditure per capita of total school population for common schools is \$15; for colored schools it is \$171.

The most pressing needs of negro education are better common schools, particularly in the rural districts. There should be more careful and complete supervision of the common schools and more teaching of the fundamental industries, agriculture, cooking, sewing, etc. Some of the larger institutions should be endowed so that, by means of extension work

and continuation schools, they would be able to come into touch with the actual needs of the masses of the people. There should be more technical and industrial schools. Particularly is there need of a normal high school where teachers may be thoroughly prepared to do the work of supervision in the common schools and where they may learn by actual practice something of the methods which are being worked out in various parts of the country for carrying the influence of the schools outside of school buildings and connecting it with the practical work and life of the community. See SCHOOL PLANT, WIDER USE OF.

The present tendency of negro education is to develop along those lines that minister to the actual needs of the people. This is seen in the growth of medical and nurse training schools, the attempt to adjust the courses of colleges and universities to present-day needs, and the growth of what is known as "extension work." In this connection it should be remembered that negro education has already contributed something to the people of the United States. Before the beginning of Hampton Institute, no educational institution gave any systematic instruction in the industries. Industrial education for the negro antedates even manual training, which was not introduced into the United States until 1876. The success of Hampton and Tuskegee institutes and of other and similar negro schools has made industrial education popular, and has not only changed the sentiment of the masses of the negro people in regard to labor with the hands, but has also helped in introducing it into Northern schools and white schools of the South. The present tendency is to connect all forms of education in some way with the daily life and needs of the people. B. T. W.

NEO-HUMANISM.—A term sometimes applied to the revival of the Hellenic ideal in German thought in the latter part of the eighteenth century. It differed from the humanism of the fifteenth century in its attachment to Greek rather than Latin culture; in a greater interest in Greek antiquities and art in general as compared simply with literary records, and in appeal to Greek culture as affording an ideal conception of life. Serenity, balance, a recognition of the inevitable limitations of life, the striving for a symmetrical development within these limits, the idea of the central place of a free play of the intellectual powers in securing this proportionate development of all human powers, are some of the traits emphasized and attributed to the Greek view of life. To these must be added the claim of spiritual and intellectual kinship with the Greeks which the Germans put forward. Winckelmann and Goethe are the chief names in this new humanism, the former with his archaeological researches, and the latter in his reaction against romanticism signalized by his *Italian Letters*. In nineteenth-century English thought, Matthew Arnold is a typical representative of the spirit of Neo-humanism in his conception of culture and his appeal for recognition of Hellenism as well as Hebraism.

In the gymnasiums and universities of Germany, Neo-humanism exercised a powerful influence. A new vigor was imparted to the classical studies, but more especially to the study of Greek. No longer content with the merely linguistic, an effort was made to imbibe the Greek spirit by a study of Greek life and literature in all its phases. In Germany this is the period of her most brilliant classical scholars. J. D.

NEO-PLATONISM.—Neo-Platonism is the final form of Hellenic philosophy as it employed, in the latest or religious phase of

ancient philosophy, the leading principles of Platonism, though not a little modified, combined with elements derived from Aristotle, Stoicism, and Neo-Pythagoreanism, and possibly even from the East, to solve, by a philosophy resting upon a religious basis, the problems of knowledge and virtue which later Stoicism had presented but could not answer. The ethical philosophies of the period immediately before and after the Christian era had ended in the confession of the impossibility of man's attaining virtue by his own effort, on account of the inherent evil in his nature, and a skeptical tendency as to the attainment of ultimate truth by any purely rational process. Neo-Platonism attempted to overcome this result by a metaphysical system which at once explained it and showed the way to attain the highest knowledge and good by a suprarational experience in which the individual obtained an immediate experience of the divine. The elements not proper to Greek thought appearing in Neo-Platonism are in harmony with the religious speculation current in Alexandria and derived possibly from oriental religions. They certainly first appear in the philosophy of Philo, and although no direct relation between that Jewish philosopher and Neo-Platonism can be traced, the resemblance must be more than a chance coincidence.

There are three schools of Neo-Platonism distinguished as to time, locality, and character. Of these the Alexandrian is the earliest and most important in the history of thought. It is the creative period of Neo-Platonic speculation and finds its expression in the works of Plotinus (204-270) and his disciple Porphyry (233-c. 304). It was at Alexandria that Plotinus developed the first elements of his system under the influence of Ammonius Saccas, the traditional founder of Neo-Platonism. It was at Rome, however, that Plotinus lived and taught in his school of philosophy. Here also Porphyry lived, editing the works of his master and teaching philosophy, not merely that of his master, but that of Aristotle, on whose work he wrote valuable commentaries. The Roman period of Neo-Platonism is by far the most interesting, as its aims were predominantly metaphysical and ethical. Religious as it was in its fundamental principles, it yet did not surrender philosophical interests to further positive religion. The Syrian school of Neo-Platonism is represented by its founder Iamblichus (*d.* 330), who degraded Neo-Platonism by exaggerated emphasis upon the magical or theurgic elements which had only been lightly touched upon in the works of Plotinus. In this phase, Neo-Platonism became less a philosophy and more a religious dogmatic system, a justification of theurgy and a guide to proficiency in magical arts. The Athenian school is represented by a group of teachers at Athens, the leading seat of the later study of heathen philosophical classics, and it flourished until

the closing of the school in 529 by Justinian. Of these teachers by far the most important was Proclus (410-485) one of the scholars. In his works we have a quasi-scholastic attempt to weld into a consistent body of doctrine the teaching of the various philosophers of the school, avoiding the alliance with positive heathen religion, as there was not longer any hope for its resuscitation. Proclus gave the form through which Neo-Platonism affected Christian Mysticism. (See MYSTICISM.) But though these three phases are clearly distinguishable in the history of Neo-Platonism, the movement was very widespread, and schools of philosophy were to be found in many cities sharing the common impulse given by Plotinus to metaphysical speculation and differing in many minor points.

Neo-Platonism came into conflict with Christianity first in the period just before the end of the heathen empire, when Porphyry attacked Christianity with vigor and great critical ability. Yet Porphyry himself turned with increasing hostility against the crudities of heathenism and was as unsparing as any Christian apologist in denunciation of the immoral mythology of heathenism. He acknowledged the personal worth and character of Christ, but denounced the practice of Christians of worshipping him. The Christian writings were to him base forgeries. But the breach between the two systems, which in metaphysical outlines had been hardly apprehended as hostile, widened, and, under the influence of Iamblichus and his teaching, Neo-Platonism began to associate its fortunes with the fortunes of paganism, and everything was done to establish paganism upon a speculative basis.

Neo-Platonism failed in several points as a system likely to become generally acceptable. Its appeal was necessarily restricted to a select few. However low it might descend with Iamblichus, it always remained a metaphysical system. It failed to meet the simple popular demand for an historic personality to whom the heart could turn. In this the nearly allied system of Neo-Pythagoreanism had an advantage. And the attempt to employ Apollonius of Tyana as such was based upon sound judgment. Then, again, the doctrine of God in Neo-Platonism was so transcendent, colorless, and vague, so much like an hypostatized zero, that it could not touch the heart. Even when the language of St. Augustine (*q.v.*) is strongly reminiscent of Plotinus, there was always the personal touch established by the Incarnation and the personality of God. The ecstasy of Neo-Platonism might be an experience for the intellectual élite, but it had no promise for the multitude.

Although Neo-Platonism was always limited in its appeal, even in the school of Iamblichus its enthusiastic adherents had hopes of making it a universal religion under the patronage of Julian (361-363). But though the philosophi-

cal religion of that emperor gave free play to the superstitious and polytheistic elements of paganism, Neo-Platonism proved a dismal failure as a popular religion. It was naturally hated and despised by Christians, but it was ridiculed and contemptuously rejected by the heathen. The dull ceremonies and joyless services prescribed by Julian after a Christian model failed to satisfy their religious cravings and habits of worship. Its interminable philosophical harangues in imitation of Christian sermons gave nothing their minds could grasp. The very failure of Julian's attempt to make Neo-Platonism the State religion led to a reaction and to that relative sobriety which characterized the later school of Athens and found its expression in the writings of Proclus.

Though Neo-Platonism failed as a religion, as a philosophy it left a permanent impress upon the Christian world. In the East, the Pseudo-Dionysius made it the basis of his mystical theology. In the West, it left an abiding impression upon the theology of St. Augustine and his followers, especially in the doctrine of God and the negative character of evil. It was revived repeatedly by both heretics and teachers of unblemished orthodoxy in the Middle Ages, being identified with Platonism. Elements were introduced through the Arabians, Avicenna and Averroës. At the time of the Renaissance it was studied afresh in the original documents. Of its teachers under the Medici, the Greek philosopher Gemistus Pletho was the most important. Marsilius Ficinus (*q.v.*) translated Neo-Platonic works. Pico di Mirandola and Reuchlin also studied it. Giordano Bruno and Jacob Bohme show its influence. Fichte and Hegel, and especially Schelling, show many affinities with the speculative elements and methods of Neo-Platonism, and it has become a common possession of various forms of mysticism.

NEPOS, CORNELIUS.—A Roman historian of the first century B.C. (c. 100-24), wrote, among other works a series of parallel biographies of famous Greeks and Romans in sixteen books (*De viris illustribus*). There remain only the part treating of foreign generals, and the lives of Cato and Atticus.

These biographies are as a rule very brief and have long been a favorite material to put into the hands of young students of Latin. The style, however, is not pure, and the tendency to abstract analysis of character renders the mill adapted to children. Their contents, too, are often dull and uninspiring. Partly for these reasons, Nepos has been read less and less in schools in recent years, except for supplementary study. When read he belongs to the second year, alongside of Cæsar. There is no lack of adequate school editions. An exhaustive study has been made of his style by Lupus (*Der Sprachgebrauch des Cornelius Nepos*, Berlin, 1876).

NERVE.—See NERVOUS SYSTEM.

NERVE IMPULSE.—See NERVOUS SYSTEM.

NERVOUS CHILDREN.—See DEFECTIVES; NEURASTHENIA.

NERVOUS DISEASES.—See MIND, DISEASES OF; NEURASTHENIA.

NERVOUS SYSTEM.—All nervous tissue in the body, whether in the nerves or in the nerve centers, forms a single connected system. Formerly the "sympathetic system," with its ganglia and nerves supplying the viscera, blood vessels, etc., was regarded as relatively independent of the cerebrospinal system; but present information indicates that the sympathetic is simply an adjunct of the other. The sense organs, though not reckoned as parts of the nervous system, are connected with the sensory or afferent nerves—the retina with the optic nerve, the organ of Corti with the auditory nerve, the taste buds with the nerves of taste, and the touch corpuscles and other sensory end-organs in the skin and throughout the body with numerous sensory nerve fibers in the mixed nerves. The muscles and many of the glands are connected with the motor or efferent nerves. Thus the *system*, as a working whole, contains, besides the nervous system, the "receptors," through which the environment acts on the organism, and the "effectors," by which the organism reacts upon the environment. The part played by the nervous system is primarily that of affording a quick means of communication between the receptors and the effectors.

Spinal Cord.—From the brain and spinal cord, nerves ramify to all corners of the body.

NERVOUS SYSTEM

The brain, protected by the skull, and the cord, extending down the back within the spine, are continuous with each other through a hole in the base of the skull. The cord appears like a large nerve, one half

to one third of an inch in diameter, with "enlargements" at the height of the shoulders and at that of the loins. The upper enlargement is the source of the nerves to the arm, and the lower enlargement of those to the legs; and they are the lower or local centers for reflexes of the limbs.

The cord is white outside, as the nerves are; but a cross section reveals something not found in the nerves, namely, gray matter. The cord is nearly divided into right and left halves by grooves or fissures extending along both its dorsal and its ventral surface, but there remains a connection or "commisure" between the two lateral halves. In each half, the gray matter shows dorsal and ventral portions or "horns," the ventral being, in the enlargements, large and fat, while the dorsal horn is always rather slender. The nerves come off from the

cord by the dorsal and ventral "roots," of which there are a whole series on either side of the cord. It is a remarkable fact that though the nerves as they run through the limbs and other parts of the body are "mixed nerves," containing both sensory and motor constituents, these are segregated on entering the cord, and all the sensory nerve fibers enter the dorsal root, close to the dorsal

horn of the gray matter, while all of the motor fibers enter the ventral roots. In fact, during the embryonic growth of the nervous system, the motor nerves grow out from the ventral

NERVOUS SYSTEM

horn of the gray matter, while the sensory nerves grow, not out from the cord itself, but from the "spinal ganglia," masses of nerve cells lying close outside the dorsal portion of the cord.

The white matter of the cord, lying outside the gray, is spoken of as divided into "columns," dorsal, ventral, and lateral. The dorsal columns are direct continuations of the dorsal roots, and consist, therefore, of sensory fibers which have come in from the nerves and are proceeding towards the brain. The lateral and ventral columns contain many sets of fibers, some conducting upwards and some down, some being short and others long.

Brain.—The brain consists of the "brain stem," a continuation of the cord, and two large outgrowths, the cerebrum and cerebellum. The brain stem lies along the floor of the skull, from back to front. Its rear or lower portion, next to the cord, is the "medulla" or "bulb"; in front of this is the "pons" and next the "midbrain"; then the "inter-brain" or "thalamus," and finally the basal

portion of the "end-brain." The great bulk of the end-brain consists of the cerebral hemispheres, which are outgrowths from the more primitive basal portion of the end-brain; the cerebellum is an outgrowth from the pons.

The nerves of the head issue from the brain stem; that to the nose from the end-brain; that to the eye from the interbrain; those to the muscles of the eyeball chiefly from the midbrain; that to the skin of the face from the pons; those to the ear and to the throat and rear of the mouth from the medulla. Where the nerves from any part enter, there are the lower centers for that part. The medulla receives the "vagus" nerve, which supplies the heart, lungs, and stomach; and the medulla accordingly contains the respiratory center and the cardiac center, as well as a vasomotor center which regulates the constriction and dilatation of the blood vessels, and a center which influences the activities of the stomach. The medulla, it will be recognized, is an extremely vital part; without it, respiration is impossible, and accordingly destruction of the medulla is, in one form or another, a favorite means of capital punishment.

The end-brain, or cerebrum, is almost sepa-

rated into hemispheres; these are, however, joined at the base, and are connected also by the "corpus callosum," a large bundle of nerve fibers, which practically unites the hemispheres into one organ. In the cerebrum, as well as in the cerebellum, the arrangement of white and gray matter is different from that which obtains throughout the cord and brain stem, in that the gray matter lies on the external surface, forming a bark or rind or "cortex." The external surface of both the cerebrum and cerebellum is much folded, with the result that the area of the cortex and the amount of gray matter are much larger than would be the case with a smooth surface. The surface of the cerebrum is spoken of as divided into the frontal, parietal, occipital, and temporal lobes, the frontal and parietal being separated by the central fissure (or fissure of Rolando), and the frontal and temporal by the lateral fissure (or fissure of Sylvius). There are many minor fissures, subdividing each lobe into convolutions or gyres. Thus, from above downward, the frontal lobe contains the first, second, and third frontal convolutions, and the temporal is similarly divided. The precentral and postcentral convolutions border the central fissure. These subdivisions have value as landmarks, but do not usually indicate inner or functional division of the brain.

Growth of the System. — The development of the nervous system begins, very early in embryonic life, with the appearance of a "neural groove" extending along the back, and a little later arching over into a tube, the "neural tube." It is the outer layer of the embryo from which the neural tube originates, but this is crowded inwards and surrounded by the growth of muscle and bone. The neural tube at its forward end becomes expanded into a series of five vesicles, which develop into the five principal parts of the brain: end-brain, interbrain, midbrain, hind-brain (including pons and cerebellum), and after-brain or medulla. In spite of the complicated form into which it grows, the neural tube remains always a tube, with a hollow extending along the spinal cord and brain stem and into each cerebral hemisphere. The hollow of the tube is expanded into the "ventricles" of the brain. Along with the neural tube, there are infolded two little strips of the external surface of the embryo, and these give rise to the sensory and sympathetic nerves and ganglia. The motor nerves arise from the neural tube itself. It is interesting to note that the retina, the sensitive surface of the eye, arises from the neural tube, and is therefore to be regarded as part of the brain; it has indeed a distinctly nervous structure.

Nerves. — The minute structure of the nervous system is more important to understand than the gross structure which has already been sketched. Microscopic study of the nerves shows them to be bundles of fibers

running parallel to each other, like wires in a telephone cable. The white matter of the cord and brain is essentially the same as the nerves, being composed of nerve fibers. The unit is the fiber, which, on microscopic examination, is seen to consist of a central core, called the axon, surrounded by one or two sheaths. In most of the nerves, each axon has two sheaths, called medullary and primitive, the latter being outside. In the white matter of the cord and brain, the primitive sheath is lacking, but the medullary is present; while in sympathetic nerve fibers the reverse is true. The medullary sheath is composed of a white, fatlike substance, which has some of the physical properties of an insulator and may have a somewhat similar function. It is this substance which gives whiteness to the white matter.

The gray matter differs from the white in the absence of the medullary sheath, and in the presence of nerve cells, which are absent from the white matter and from the nerves, except for the sympathetic and spinal ganglia attached to the nerves. The fine branches of the nerve cells and of the fibers are also confined to the gray matter. The gray matter consists of numerous nerve cells embedded in a meshwork of minute fibers. It presents a most complicated problem to the microscopic anatomist who would analyze it; but, considering the difficulties involved, extraordinary progress has been made. It is found that every nerve cell, if at all fully developed, sends out a long, slender branch, the axon, which, becoming invested with a medullary sheath, emerges from the gray matter into the white, and appears there as a nerve fiber. The axon, in other words, is a branch of a nerve cell, and there seems little reason to doubt that all the axons of the nerves and white matter originate from cells in the gray matter. Besides the axon, the nerve cell has other branches of a different sort, short and branching like a tree,

from which fact they have received the name of "dendrites." These differ from the axon, also, in receiving no medullary sheath and in never extending beyond the bounds of the gray matter. The axon, in general, branches much less than the dendrites, and its branches (called "collaterals") are slender and usually at right angles to the main trunk. But the axon, and each of its collaterals, finally comes to an end in a tuft of fine branches, always turning into the gray matter to terminate in this manner; there are no terminations of axons within the white matter. Apparently the numerous fine fibers of the gray matter are accounted for as dendrites and fine terminations of axons; and if so, we can conceive the gray matter as consisting of nerve cells embedded in a dense mat of their own branches and of the branches of other cells and axons.

Under high magnification, the inner structure of the nerve cell shows a nucleus, similar to that found in every living cell, and — what is peculiar to the nerve cell — numerous delicate fibrils, coursing in different but definite directions through the cell body and out into the axons and dendrites. In the axon, these fibrils run strictly parallel to one another. It is believed by some authorities that the fibrils are the ultimate conducting agents. The cell body and larger dendrites show another feature that is absent from the axon: granules of triangular or spindle-shaped outline, called the chromatic bodies. The substance which gives this mottled or "tigroid" appearance to the nerve cells may be of the nature of fuel; at least, it has been observed to become diffused throughout the cell during prolonged activity, so that the fatigued nerve cell shows a diffused instead of a mottled color. Certain drugs and abnormal conditions also produce this condition, which is called chromatolysis.

Neurones. — A nerve cell, with its axon and dendrites and all the ramifications, is often called a *neurone*. This term is bound up with the "neurone theory," according to which the neurones remain separate one from another, and are not united into continuity. In embryonic development, the nervous system starts as a collection of unbranched cells, which later put forth axons and dendrites; and the question is whether the branches of different cells unite in the course of their development into a continuous meshwork. The best methods yet available fail to show any anastomosis of the branches of different nerve cells, though there is sometimes close adhesion. But some authorities oppose to the neurone theory a "fibrillar theory," according to which the minute fibrils already mentioned pass freely from one neurone to another, and, possibly, form in the interstices between neurones a network of the utmost tenuity, which, these authors think, is worthy to be called the essential part of the gray matter, since it would

be the means of making connections between different nerve fibers and so between different parts of the body. As the evidence stands today, the neurone theory has a better standing and wider acceptance than the fibrillar theory, for the passage of fibrils from one neurone to another, or their presence in the spaces between neurones, has not been demonstrated.

Function of Nervous System. — The primary function of the nervous system is, without doubt, to conduct not materials, as the circulation does, but something in the nature of messages or stimuli, capable of arousing activity in the organs to which the nerves run. The "message" carried by the nerve is called, in the absence of any sure knowledge of its real character, the "nerve impulse." It may be an electrical change that moves along the nerve, since such a change can be detected in an active nerve, and nothing else — movement, heat, or chemical action — has been demonstrated. The speed of the nerve impulse can be measured, but in man the values obtained have varied all the way from 100 feet to 350 feet per second, with the more recent and improved methods favoring the higher values.

The function of the nerve fiber, and accordingly of the nerves and white matter, is certainly to conduct and nothing more. Axons appear to be insulated one from another in the nerves and white matter, so that no communication from sensory to motor, no switching or distribution of impulses, occurs except in the gray matter. It is likely, though not universally believed, that all nerve fibers act much alike, being indifferent conductors. What is called the "specific energy of a nerve" refers to such facts as that a jarring or any sort of stimulus to the optic nerve produces only sensations of light; but the specific energy may reside not in the optic nerve, but in the visual area of the cortex to which the nerve leads. The white matter and the nerves seem to be mere passive conductors. Everything that is active or variable with conditions or modifiable by experience is an affair of the gray matter. An adequate conception of the action of the gray matter can certainly not be formed in the present state of knowledge; but what seems a probable outline of its mechanism can be based on its structure along with the notion that the fundamental function of all nervous tissue is to conduct impulses.

Where formerly the nerve cells were looked upon as the essential things in the action of the gray matter, of late the view has gained force that they are nutritive in function, serving to keep their branches alive and in good working condition, and that the branches which interlace in the gray matter do the actual work. There is, in any minute portion of the gray matter, an intermingling of the dendrites of the cells located there with the terminations of axons which enter from other parts. For example, the axons coming into the cord or

brain stem from a sense organ terminate within some mass of gray matter, in close contact with the dendrites of the cells of that gray matter; and in some cases it is perfectly clear that the incoming axons must transmit their activity (their "messages") to the dendrites of these cells. It is probable that the dendrites are receptive and the terminations of axons excitatory or transmissive; so that a nerve impulse, entering the gray matter by an axon, passes from the terminations of this axon to the dendrites of another cell, and thence to the axon of that cell and so away to some other part of the gray matter or to some organ outside. The function of the terminations of axons and of the dendrites seems, therefore, to be that of effecting connections.

Since an axon, in its termination, may make connections with the dendrites of several cells, there is a chance for that distribution of influence which is the essence of coordination. Since several axons may terminate in proximity to the dendrites of a single cell, there is opportunity for the convergence and combination of impulses. The importance of a convergence of neural paths is especially seen in facilitation and inhibition. Two stimuli, acting on different sense organs, may reinforce or facilitate each other's action; or, one stimulus may prevent or inhibit the action of another. Thoughts and emotions, having their seat in the cerebrum, may either hasten or slacken the rate of breathing; and this means that they have reinforced or inhibited the reflex effect of sensory stimuli reaching the respiratory center in the medulla. There must be in all such cases a convergence of influences from two or more sources upon that part of the gray matter which is directly connected with the effector organs.

Sleep, drowsiness, and unconsciousness under the influence of drugs are conditions primarily of the gray matter, and are probably to be conceived as a temporary impairment of the connections between axons and dendrites. Learning, a process which seems to concern almost entirely the cerebral cortex, may be conceived as consisting in the improvement of connections through use, and forgetting as an atrophy of connections through disuse. Exercising dendrites or the terminations of axons may probably cause them to grow and improve in condition for work, as is known to be the case in muscular tissue.

The neurone theory, though primarily concerned with the structure of the gray matter, has proved a great aid in reaching a conception of the function. The name *synapse* has been applied to the junction, without continuity, of the termination of an axon with the dendrites of another cell. The proximity of the two may be very great, yet it does not amount to continuity such as holds between different portions of the same neurone. There is always a breach of continuity, or "surface of separa-

tion" between the interlacing branches of two neurones. Hence, it is probable that conduction through the gray matter is much slower than along a nerve fiber, and that impulses go in only one direction through the gray matter. The synapse has a sort of valve action on nerve impulses, permitting them to pass only in the direction from termination of axon to dendrites. The synapse is the susceptible part of a neural path or connection, where varying influences, such as are seen in facilitation and inhibition, take effect. The synapse it is, according to this conception, which is improved by learning and which deteriorates by disuse.

Since all sensory axons lead into the gray matter, and all motor axons originate in gray matter, the simplest form of action involving the nervous system is the reflex, in which a stimulus to a sense organ, acting through a sensory nerve, arouses to activity the gray matter from which issue the motor nerves to the reacting muscles. The "reflex arc" consists of the sensory or afferent nerve fiber, the synapse between this and the dendrites of a motor nerve cell and the axon of this cell. This is the simplest possible reflex arc, but it is probable that most reflexes have longer and more elaborate paths than this.

Localization of Functions.—It is clear from all that precedes that the nervous system does not act as a mass, in the way that the liver may be thought of as acting, but in detail, by means of particular paths and connections. Hence a large share of the vast amount of study that has been given to the brain and cord is concerned with the localization of function. In the white matter attention has been directed to disentangling the tangle of bundles that course through it, and that are called *tracts*. Purely anatomical methods need to be supplemented by physiological and pathological methods in order to trace out a tract from its origin, *i.e.* the portion of gray matter containing the cells from which its axons arise, to its termination, *i.e.* the portion of gray matter which its axons finally enter and where they terminate. Among sensory tracts in the cord may be mentioned the dorsal columns, which are apparently concerned with the muscle sense and not with the cutaneous senses, and the "spino-thalamic tract" in the lateral column, which is apparently the path of cutaneous sensation. Among motor paths, the one best worth mentioning is perhaps the cortico-spinal or pyramidal tract which, originating in the giant cells of the motor area, passes down through the brain stem, "decussates" or crosses, for the most part, in the medulla, and runs down the cord in the lateral column, terminating all the way along in connection with the motor cells of the ventral horn. "Decussation" is a curious fact regarding the tracts that lead into or out of the cerebrum. The decussations occur in various

parts of the cord and brain stem, but all have for their effect to bring the right half of the body into connection with the left hemisphere and the left half of the body with the right hemisphere. Therefore, the left hemisphere controls the movements of the right hand, and also receives sensations from it.

The first indication of a localization of functions in the cerebral cortex — since the earlier effort of the phrenologists to localize the various faculties had proved abortive — was Broca's announcement that the third frontal convolution in the left hemisphere was connected with speech, and that its injury entailed aphasia (*q.v.*). Next, the "motor area" was roughly located, and since then areas for vision, hearing, touch (in the broad meaning), and smell have been determined. These sensory and motor areas are directly connected by fibers with the lower centers, which in turn are directly connected with the sense organs and muscles. The visual area, adjoining the calcarine fissure on the median surface of the occipital lobe, receives impulses from the retina, and any seen object that influences the cortex acts first on this area, and then, by association fibers, on other parts of the cortex. All sensory impulses first reach the cortex in certain limited areas and radiate thence by the very numerous association fibers to other parts. The motor area, extending along the front side of the central fissure, is the origin of the corticospinal and similar tracts, and the principal gateway through which the influence of the cortex is exerted on the muscles. The motor area must be aroused by association fibers whenever the movement of the hand is directed by the eye or ear, or by some internal thought. The visual area in the occipital lobe, the auditory area in the first temporal convolution, the "touch" or "somesthetic" area just behind the central fissure, and the olfactory area in the pyriform lobule, along with the motor area, cover only a small fraction of the cortex, and the remainder is by no means so certainly mapped out. In general, it appears that regions immediately adjoining a sensory area have functions closely related to that of this area, but "higher" or more intellectual. Thus the recognition of familiar objects by sight, reading, etc., depends on the occipital lobe; and the understanding of heard speech and the appreciation of music depends on a temporal region near to the auditory area. The region immediately behind the somesthetic area seems to be concerned with the perception of form, texture, size, weight, etc., by touch; and the region just in front of the motor area may have, besides its function of speech, control of writing and other similar coordinations. Even with these vaguer localizations added to what is clearly established, a large share of the cortex still remains uncharted.

The size or weight of the brain probably

influences mental capacity, though the correlation is far from close. The brain develops earlier than any other organ except the sense organs; it is always forward in foetal life, and at birth has fully a quarter of its adult weight; this increases to two thirds during the first year, and to nine tenths at four years; after which there is a slow increase to about the fifteenth year. The adult weight varies considerably in different individuals, with an average not far from 1400 grains (50 oz.); in women it is about 10 per cent less (See GROWTH). Studies of the cortex at different ages seem to show that the little fibers — dendrites and terminations of incoming axons — which constitute the working parts continue to grow till the fortieth year at least. In old age there is a shrinking in the weight of the brain. R. S. W.

NERVOUSNESS. — See NEURASTHENIA.

NETHERLANDS, EDUCATION IN THE.

— The Kingdom of the Netherlands is divided into eleven provinces; namely, North Brabant, Guelders, North and South Holland, Zealand, Utrecht, Friesland, Overijssel, Groningen, Drenthe, and Limburg. The names recall the independent dukedom, bishopric, and counties whose contests mark the early history of the country. The area of the kingdom is 12,648 square miles, and its population in 1910 was 5,945,429. It is a kingdom of large towns, having no less than thirty with populations above 20,000. The colonial possessions of the Netherlands, which have been a source of wealth, comprise an area of 783,000 square miles and a population of approximately 38,000,000.

The religious denominations have exercised great influence in educational matters. The royal family and the upper classes, generally, belong to the Reformed Church, which numbers above 2,588,000 adherents; other Protestant denominations comprise 746,000. The Roman Catholics number 2,052,781; Jews 106,402; Jansenists, 10,082. Complete religious liberty prevails, and each denomination receives an annual subvention from the treasury. The people of the Netherlands are nearly all natives by birth and ancestry, foreigners forming only 1 per cent of the total.

Historical Development. — The first school within the limits of what is now the Netherlands, so far as the records show, was established at Utrecht by Willebrord, missionary from England to the Frisians. He was ordained Bishop of Utrecht in 695 at the instance of Pepin, father of Charlemagne, who desired to found a bishopric in that part of Friesland which had been brought under the Frankish rule. Thus Utrecht became a center of enlightenment in the empire of Charles the Great. The monastery schools of Egmond, Nijmegen, Middleburg, Zeeland, and Adouwert were famous in the ninth century. The breaking up of the Empire after the death of Charles the Great was followed by invasions of the Northmen and the consequent rise to power of the great nobles who opposed their ravages, and of the towns to which the people fled for safety. It was in the eleventh century that the Count of Holland by his successful resistance to the Emperor, Otto II, gained overlordship in Nether-Lotharinga; and from William I, the Count of Holland who bore a notable part in the fourth crusade, the chief towns secured charters that guaranteed civic liberty and privileges to the burghers. Among the latter was the right to establish schools, and thus early in the thirteenth century, beside the Cathedral and monastery schools, appeared "public" or town schools. These were styled *School en Schrijfambacht*, *Schoolen en Kostern* (school and writing office; school and clerks' houses). The *schoolmeesters* (schoolmasters) were looked upon as professional men. They formed distinct guilds and fraternities and were highly respected by their fellow citizens. Public schools were divided into *grote en bijschoolen* (higher and lower schools). Latin was taught only in the higher schools, which had generally the largest number of pupils. One of them, the school of Zwolle, numbered 1000 pupils from the Netherlands and Germany. The Brethren of the Common Life (*q.v.*), whose first school was founded by Gerhard the Great of Deventer (1340-1384), did much for the promotion of education in different European countries. Thus the different classes of schools which maintain their distinctions under the present system of public instruction, namely, church schools, town or public schools, and schools belonging to private societies, all originated before the close of the fourteenth century.

In the century following, the provinces were controlled by the Dukes of Burgundy; but although their political life was stifled, the arts and the learning of the Renaissance flourished, especially in Flanders and Brabant. The States-General of the provinces, instituted by Philip of Burgundy, became, in time, the embodiment of their national will and purpose. From the last of the Burgundian rulers, the Duchess Mary, the cities secured the "Great Privilege" (1477) which affirmed their right to hold diets, reserved to the Estates a voice

in the declaration of war and the imposition of taxes, established one high court of justice for Holland, Zealand, and Friesland, and made Dutch their official language. Thus the leading provinces entered upon the century of struggle against Charles V and Philip of Spain with a measure of internal union. This period was marked by a wonderful outburst of talent and learning. The fame of great scholars, Erasmus, Grotius, Barneveldt, to name only those who most profoundly affected human thought, is linked with that of William the Silent, founder of the Dutch Republic, and of his son Maurice, its military genius. The University of Leyden (*q.v.*), the bulwark of Protestant doctrine in the United Provinces, was founded by William the Silent in 1575 to commemorate its heroic defense against the Spanish besiegers. Ten years later (1585) a second university was created at Francker, and in the seventeenth century three universities were added; namely, Utrecht, 1638; Groningen, 1644; and Herderwijk, 1648. Francker and Herderwijk were closed in 1811.

The fall of the Dutch Republic is connected, indirectly at least, with the bitter controversy between the extreme Protestant sects, the Arminians and the Calvinists, which broke out in the University of Leyden early in the seventeenth century. The rivalries and contests of the different provinces completed the disaster, and the political life of the United Provinces became inextricably mingled with that of neighboring Powers. Nevertheless, a certain distinction was preserved to the Provinces by the achievements of their university teachers and by the refuge they afforded to men of science and learning exiled from their native lands.

Antecedents of the Present System of Primary Education. — The early zeal for education in this kingdom had little effect upon the common people; the first movement in their interests was begun by John Nieuvenhuysen, a Mennonite clergyman of Groningen, who founded in that city, in 1784, the Society of Public Good (*Maatschappij tot Nut van't Algemeen*), whose object was to promote elementary instruction — moral, social, and religious. The society established schools, published simple textbooks, and awakened great interest in the subject of popular education.

At this time the provinces were comprised in the Republic of Batavia (1795-1806), and the political spirit gave impetus to the efforts of the society. A special commissioner, the celebrated Van den Ende, was appointed to devise means for promoting the general instruction of the people. The outcome of his labors was the law of 1806, which forms the basis of the primary school system. Napoleon had already extended his conquests to Holland, and a few months after the promulgation of the law the Emperor made his brother Louis king over the province. Fortunately, however, Louis had no disposition to interfere with the

educational movement. In 1810 he abdicated, and Napoleon then incorporated the provinces into the Empire and took measures for assimilating their educational system to that of the Imperial University. The report of Cuvier, one of the two commissioners appointed for this service, was so favorable to the system of primary education that it was continued with Van den Ende as its chief. After the fall of Napoleon and the establishment of the kingdom of the Netherlands, comprising Holland and Belgium, a decree was issued (March 6, 1815) which ordered that the school law of 1806 should be the basis for further regulations concerning public instruction. This early measure settled for the Netherlands the principle of public inspection of schools. It provided for the appointment of school inspectors who were to constitute in each province a permanent school board. The largest communes were required to form local school boards. No school could be established without the special permission of the provincial or communal authorities. The course of primary instruction comprised reading, writing, arithmetic, Dutch, French or other modern language, geography, and history. Schools were to be entirely independent of ecclesiastical influence. The schoolbooks were to be authorized by the school boards. Nobody was allowed to teach without passing the prescribed examinations.

The intervention of the State in education and the prohibition of religious teaching in the schools were vehemently opposed by the Roman Catholics, who formed the majority in the southern provinces (the present kingdom of Belgium). Their dissatisfaction grew from year to year, and finally gave rise to the revolution of 1830, which was followed by the permanent separation of Belgium from Holland. Before this event the school system had received two important extensions: In 1816, through the influence of M. Van den Ende, a normal school was established at Haarlem as an integral part of the system, and government recognition was extended to the normal school at Groningen, previously established by the Society of Public Good. Up to this time the teachers of Holland had been trained by serving an apprenticeship, from the age of fourteen to sixteen or eighteen, as assistants in the larger schools. During the same time they were given instruction for an hour every evening. This pupil-teacher system, which was subsequently introduced into England, never developed its worst features in Holland and in a restrained form is still employed there as a means of training. The pupil teachers form no part of the regular school staff.

The second measure of extension was the establishment of a higher class of primary schools, the *burgerscholen*, to meet the demand of the middle classes that the State should provide schools suited to their children. The law of 1806 had placed public schools and pri-

vate schools on the same basis as regards inspection by the state and the qualification of teachers. Fees were charged in the public schools, but free provision was authorized for poor children, and thus the public schools became in practice charity schools, and the middle classes, who bore the greater part of the school tax, were forced to patronize the more expensive private schools. The higher order of public schools, established in response to the natural demand of the middle classes, included modern languages, French and English, as well as the sciences, in their curriculum. These burgher schools were condemned in Cuvier's Report as superficial and tending to draw students away from more solid branches. Time has shown that they anticipated, in a measure, the modern type of secondary school which is now found in every country.

Although the northern provinces were strongly Protestant, there was a Roman Catholic minority which showed the same opposition as the Belgians to the purely secular school system. The ultra-Protestants were in accord with them on this point and both together succeeded in restoring a measure of clerical influence to the schools. A royal decree of January 2, 1842, ordained that the religious faith of candidates for the teaching service should be taken into account, and authorized the examination of textbooks by the clergy before they should be adopted. Religious instruction was still excluded from the course of study, but the clergy were allowed the use of the schoolrooms for that purpose before or after the school hours.

The constitution of 1848, which replaced the earlier constitution of 1815 and is still in force, comprised the following clauses respecting education: Public instruction shall be an object of incessant care on the part of the government. Public instruction shall be regulated by law, with due deference to all religious creeds. The legal authorities shall provide for sufficient public elementary instruction throughout the kingdom. Instruction is free, and it is to be under the supervision of the secular authorities, whose functions shall be regulated by law. A report on the state of higher, middle class, and elementary instruction shall be submitted to the States-General (legislature) every year by the Crown (Art. 194).

The School Law (1857).—In accordance with the constitutional provisions, reports and projects of law for the regulation of elementary schools were submitted, but it was not until 1857 that a law dealing with the subject was successfully carried through the legislature. The underlying principles of the law as regards the scope and support of elementary schools and the qualification of teachers are as follows:

Art. 1. Elementary instruction is divided into ordinary and more extended instruction. Ordinary instruction includes reading, writing, arithmetic, the Dutch language, history, the rudiments of natural

philosophy, and singing. The more extended instruction is considered to include the rudiments of modern languages, of mathematics and agriculture, gymnastics, drawing, and needle work.

Art. 2. Elementary instruction may be given either in schools or in the dwellings of the parents or guardians.

Art. 3. Public schools are those established and maintained by the communes, the provinces, and the government, severally or in common; all others are private schools. Subsidies may be granted to private schools on the part of the communal, provincial, or state authorities. Schools thus assisted shall be open to all children, without distinction of religious creed. . . .

Art. 6. Nobody is allowed to give elementary instruction who does not possess the proofs of capacity and morality. Foreigners must have a special permission from the government. . . .

Art. 8. Any person giving elementary instruction without being qualified shall be prosecuted. . . .

Art. 12. For the education of teachers there shall be at least two state training schools. The education of elementary school teachers shall be promoted by the government as much as possible.

Art. 16. In every commune elementary instruction shall be given in a certain number of schools, sufficient for the number and requirements of the population, and the schools shall be open to all children without distinction of religious creed.

In addition to the essentials set forth in the articles above quoted, the law authorized the State to intervene if communes neglected its demands, determined the maximum number of pupils allowed for one teacher, the minimum salary for head teachers and for assistant teachers; and the mode of examining and certifying teachers, both men and women. The appointment of teachers was left to the communal authorities, but they were regarded as State officials and were entitled to pensions from the government under the following provision of the law:

Art. 26. The right to a pension is acquired after an honorable discharge at the age of sixty-five, and after forty years' service. A pension may also be granted to those who after ten years' service have become invalid. Those who have not received an honorable discharge forfeit their right to a pension.

The expenses of elementary schools were to be borne by the communes; fees were authorized in all schools, but free tuition was required for indigent children. It was further provided that the State should give special aid to poor communities for the establishment of primary schools.

The system of school inspection provided by the earlier law of 1806 was continued and strengthened under the law of 1857. The general supervision of education throughout the kingdom was committed to the Minister of the Interior, who is represented by provincial and district inspectors in the exercise of the supervisory functions. The duties of inspectors, both State and local, were minutely prescribed in the law.

When the law of 1857 was pending in the legislature, the question of religious instruction was the chief subject of discussion. In the end the nonsectarian character of the schools was maintained; but it was expressly provided in the law that:

The system of education shall be made conducive to the development of the intellectual capacities of the children and to their training in all Christian and social virtues. The teachers shall not teach anything inconsistent with the respect due to the religious opinions of others. Religious instruction is left to the several religious denominations. The schoolrooms shall be at their disposal for that purpose out of the regular school hours. [Art. 23]

With a single exception the main provisions of the law of 1857 have proved satisfactory to all parties, and the subsequent laws of August 17, 1878, and December 8, 1880, have simply improved the system by strengthening the inspection service and raising both the standard of qualification and the minimum salaries for teachers.

The status of private schools, as determined by the law of 1857, has been the subject of bitter controversy and has been modified repeatedly as the opposite parties, Liberal and Conservative, have come into power. The law of 1878, enacted by the Liberals, ordered that every school receiving a subsidy from the State, however small, should be considered a public school and should be subject to the same regulations. The part of the State in the school expenses was fixed at 30 per cent for all schools classed as public. The Conservative party came into power in 1883, but it proved difficult for them to obtain subsidies for sectarian schools. In 1889 this was indirectly accomplished by including the proposals in a financial bill. This measure provided that the State appropriation, which had been fixed at 30 per cent of the total school expenditure by the law of 1878, should be proportioned to the number of pupils, alike in public and in private schools. Fees are required in all schools, but not to exceed the actual cost per pupil and are to be remitted in case of necessity. The additional appropriation for school buildings was fixed in every case at 25 per cent of the total cost. While State subsidies were thus sanctioned for private schools, the communes were prohibited from making appropriations to them. The immediate effect of this measure was to increase the number of parochial schools and reduce the attendance upon public schools.

The denominational difficulty having been settled by the law of 1889, support was secured for the compulsory principle which was introduced by a law of July 7, 1900, carried by the Liberals. Parents and guardians were required to secure the education of their children and the duties and powers of school attendance committees were accordingly extended.

Elementary Education.—*School administration and supervision.*—The State administration of schools is in charge of the Minister of the Interior; at the head of the inspection service are three general inspectors; and subordinate to them are twenty-five district inspectors; ninety-four inspectors of arrondissements, and from 200 to 300 communal

NETHERLANDS, EDUCATION IN

committees. All these officials are appointed by the sovereign and receive their salaries from the State. The communal committees maintain close relation with the local school boards and local supervisors and report to the provincial inspectors. The latter make annual reports to the Minister of the Interior, and at his summons meet as an advisory council to deliberate upon the interests of elementary education.

The local administration of the schools rests upon the local civil authorities, communal burgomaster and council. The law requires that a school board shall be formed in every

NETHERLANDS, EDUCATION IN

commune, but small communes may unite to form a board in common. The school board maintains constant supervision over the schools and reports to the communal council their condition and needs.

Statistics.—Primary instruction (*lager Onderwijs*) includes day schools for children of the obligatory age (seven to thirteen years); repetition or continuation schools; and evening schools. Elementary schools for defective children and infant schools are partly supported by public funds, but they do not come under the same regulations as the ordinary schools. The following statistics pertain to the latter only.

DAY SCHOOLS	NUMBER OF SCHOOLS	ENROLLMENT			TEACHERS		
		Boys	Girls	Total	Men	Women	Total
Public	5229	313,000	249,824	562,824	11,100	5201	16,301
Subsidised private	1880	150,347	190,971	341,318	4997	4775	9772
Non-subsidised private	127						
Total	7245	463,347	440,795	904,142	16,097	9976	26,073

The 2016 private schools in the above table were classified as—Charity and orphan schools: Protestant, 30; Roman Catholic, 31; Jewish, 2. Corporate schools: Protestant, 949; Roman Catholic, 867; Jewish, 2. Private schools: Protestant, 54; Roman Catholic, 10; other schools, 71.

The number of children between the ages of seven and thirteen enrolled in the schools January 15, 1910, was 727,854, which was 95 per cent of the total number of children of the ages named. The small number of children between seven and thirteen years of age not enrolled on the date mentioned were under the supervision of the school authorities. The total number of pupils having free instruction in 1909 was 277,792 or 30 per cent of the total enrollment. Boys and girls attend the same school and are instructed together.

The classification of the teachers and number in each class were as follows:—

PUBLIC SCHOOLS			
MEN		WOMEN	
Head teachers	3195	Head teachers	63
Teachers	7903	Teachers	5138

PRIVATE SCHOOLS			
MEN		WOMEN	
Head teachers	1148	Head teachers	535
Teachers	3517	Teachers	4240

The regulations call for one head teacher for every school; if the number of pupils is

between 41 and 90 there must be a second teacher; if from 91 to 144 a third, and for every additional 55 pupils, an additional teacher. The minimum salary for head teachers ranges from 750 fl. (\$301.50) to 950 fl. (\$382); for teachers from 500 fl. (\$201) to 700 fl. (\$281.40). The salaries depend in a measure upon the number of pupils.

All teachers who have reached the age of sixty-five years, and those who are mentally or physically disabled, after ten years' service, are entitled to pensions. The pensions are paid quarterly, and amount to one sixtieth of the annual salary for each year of service, but must never exceed two thirds of the former salary.

The enrollment in the other schools included in the primary system, 1910, was as follows.—

EVENING SCHOOLS	PUPILS		
	Male	Female	Total
Public	2796	2132	4928
Private	1477	1055	2532
Total	4273	3187	7460

The pupils in the elementary evening schools are generally also attending day schools; hence the former are an adjunct to the latter.

CONTINUATION SCHOOLS	PUPILS		
	Male	Female	Total
Public	26,169	13,360	39,529
Private	5344	1374	6718
Total	31,513	14,733	46,247

NETHERLANDS, EDUCATION IN

The regulations require that primary schools shall be open without intermission the whole year, except on holidays. During class hours the master shall be present from the opening of school to closing; he must not engage in extraneous duties, nor absent himself except in cases of absolute necessity. Pupils must be enrolled, as far as possible, for fixed terms. An examination is held once a year at each school and qualified pupils are then promoted from the lower to the higher grades; if circumstance permit, rewards are given for diligence and merit. A deserving pupil, when leaving school after completion of the course of study, is presented with a certificate of honor. A code of regulations must be drawn up for each school, and this, whether written or printed, is displayed on the board, hung up in the classroom, and from time to time is read and explained by the master. School savings banks are maintained in nearly all schools.

Religious Instruction.—The lessons in religion are entrusted entirely to ministers and special teachers of theology. Regular teachers must refrain from teaching, doing, or permitting anything at variance with the respect due to the religious convictions of other sects. A teacher guilty of offense in this respect may be suspended for a term not exceeding one year, but in case of repetition of the offense he may be suspended for an indefinite period from the duties of a public-school teacher. The introduction of religious instruction into common schools is no departure from the principles of the law. It has been allowed on account of the difficulties experienced by parents who cannot obtain religious instruction for their children in other suitable places, but precautions are taken so that religious teaching shall not interfere with other lessons.

School Buildings.—The modern school buildings are commodious and well planned and the furnishings excellent. The sanitary conditions of the buildings are strictly regulated, and in a few cities the schools are supplied with bathing facilities. In fifty-eight communes medical inspection of schools is maintained.

Expenditure for Elementary Schools.—The total expenditure (current and capital) for elementary schools amounted in 1909 to 33,790,839 fl. (\$13,583,917). Of this amount the State bore 62 per cent; the communes 28 per cent; and school fees, examination fees, etc., the remaining 10 per cent. The fees are small, often as low as four cents a week, and ranging up to twenty cents. The expenditure was equivalent to \$14.18 per capita of the enrollment (957,839) in the elementary schools, i. e. day, continuation, and evening, and to \$2.32 per capita of the population. There were also expended 39,124 fl. (\$15,728) in the support of four public, and three private schools for the feeble-minded, and

NETHERLANDS, EDUCATION IN

20,908 fl. (\$8,405) for a school for idiots. Of the latter amount only 6000 fl. were from public appropriations.

The provision of elementary instruction is completed by infant schools (*Bewaarscholen*) which are chiefly private in character. In 1910 they numbered 165 public, enrolling 30,073 children, and 1092 private with an enrollment of 102,970. This would raise the total number of children at school to nearly 18 per cent of the population.

Normal Schools.—The need of special preparation for teachers was recognized by the Society for Public Good and was impressed upon the authorities from the time public elementary schools were first established. The school law of 1857 provided that two State normal schools should be maintained, and subsequent laws, supplemented by general regulations, have greatly increased the provision for this work. In addition to the normal schools and normal classes maintained by the State, both schools and classes of this order are established by communes and by private bodies. These receive aid from the State if they comply with the official requirements. The importance of the service is recognized by the entrance examinations and by the final examination which entitles to a diploma. The standard of qualification for directors and teachers, and in the case of State normal schools appointments to these positions, must be confirmed by the sovereign.

The courses of study and training in a complete normal school cover four years. The subjects included are writing, arithmetic, composition, the Dutch language, general and national history, geography, natural science, singing, violin and piano, principles of the French, German, and English languages; mathematics, pencil drawing, gymnastics, agriculture, theory of teaching and pedagogy. Teachers must require all students to attend religious instruction, which is given at stated hours, and also their respective churches. Books and school material are furnished free of cost. Normal schools for young men are day schools; those for young women are generally boarding schools.

Statistics.—The salient particulars respecting these schools and classes as reported for 1910 are summarized in the tables on following page.

There were in addition to the above fifty-nine students (forty-five young men, fourteen young women) in training under the head teachers of schools. Of these seven men and one woman passed the diploma examination.

Special courses of training are maintained by the State, communes, and private associations for those intending to qualify as teachers of gymnastics, drawing, manual work, agriculture, etc. Candidates for appointment as principals of schools must pass a higher examination than that for ordinary teachers.

At Leyden there is a college for the training of kindergarten teachers, the only school of this class which is subsidized by the State. It receives from this source 3500 fl. (\$1407) annually and from the city 2000 fl. (\$800). In consideration of these funds, the college supplies teachers for the kindergarten schools of the city without charge. In addition to twenty-five resident students there is an average attendance of seventy day students. A noticeable feature of the training is the adaptation of the Froebelian methods and material to the conditions of child life in the kingdom.

Secondary Education — Secondary education (*middelbaar Onderwijs*) is organized in accordance with a law of May 2, 1863, amended by laws of June 28, 1876, and April 25, 1879. Included under this head are: the burgher schools, higher burgher schools, agricultural schools, and industrial, trade, and technical schools. As in the case of primary schools, the secondary institutions may be of either public or private origin.

Supervision. — The Minister of the Interior, the supreme educational authority, exercises his control of this department through the agency of three general inspectors who are appointed upon his recommendation by the sovereign; one of these has special superintendence of the State agricultural schools. Local committees are appointed by the commercial councils with the approval of the minister, for the immediate supervision of public secondary schools. In the case of industrial or technical schools for girls, women are generally appointed on the boards. The supervision of the higher burgher schools is committed to their respective directors.

Teachers — Only persons holding a diploma from a university or from a State examining board, and a testimonial of good moral standing, as required by law, are allowed to engage in secondary instruction. From this rule are exempted (1) persons who instruct children of one family only; (2) those who do not make teaching their profession but have obtained royal authority to teach without remuneration (members of religious orders). Directors and teachers of secondary instruction must receive authorization from the Minister of the Interior before they can be appointed to a position in any public or private institution, or for giving private lessons. Directors and teachers of higher burgher schools supported by the communes are appointed by the local council from a list of eligible candidates recommended by local authorities. Only male teachers are employed in the higher burgher schools. The teachers of secondary schools receive pensions upon practically the same conditions as those of primary schools.

Scope of the Burgher and Higher Burgher Schools. — The burgher schools, intended particularly for the children of tradesmen, mechanics, and agriculturists, are divided into day and evening schools. The course of study of the day schools extends through two years and embraces the following branches: Mathematics, physics, chemistry, theoretic and applied mechanics, natural history, elementary principles of technology and agriculture, geography, history, the Dutch language, political economy, drawing, and gymnastics. In each community of 10,000 inhabitants or more, one burgher school at least must be established by the communal authorities; but the burgher day schools

NETHERLANDS, EDUCATION IN

are giving place to higher burgher schools and hence the lower grade is represented chiefly by evening schools.

The higher burgher schools are divided into schools with five years' course and schools with three years' course. The law requires that there shall not be less than twelve higher State burgher schools in operation in the country, and in at least five of these the course must be of five years' duration. The schools are fully equipped with laboratories, and with illustrative museums and are distinguished for the methods and thoroughness of the instruction in science and modern languages. The actual scope of the schools of this class is illustrated by the typical program given below.

PROGRAM OF THE STATE HIGHER BURGHER SCHOOLS AT UTRECHT

Candidates for admission to the higher burgher schools must be at least twelve years of age, and must pass an entrance examination. Promotion from one class to a higher is made by examination, and at the termination of the course the students are examined by a government board: if successful, they receive a cer-

NETHERLANDS, EDUCATION IN

tificate which has great value for those seeking commercial or civil appointments.

For the latest year reported (1910) there were 81 higher burgher schools, of which 27 were State schools, 47 communal, and 7 private. The total number of pupils was 10,663, of whom 2347 were girls. For the final examination 1839 pupils were presented; the number who passed was 925, including 146 girls. The number of teachers was 1402; of these 395 had the Doctor's degree; 21 that of *candidaat* (corresponding to the French *licencé*), 869 had special diplomas. There were also 15 secondary schools for girls maintained by communes or private bodies, enrolling 1646 pupils. This makes a total of 3993 girls in the secondary grade of studies.

The salaries of directors of the higher burgher schools range from 2750 fl. to 4000 fl. (\$904.80 to \$1608); salaries of teachers from 1000 fl. (\$402) to 3050 fl. (\$1225). The total expenditure for the schools of this class in 1909 was 1,922,770 fl. (\$772,954). Of this amount 12.6 per cent was covered by State appropriation; the balance, by communal appropriations and fees.

The diploma of the higher burgher school is required as a preliminary qualification for engineers, architects, and technologists who aspire to enter the State service. The diploma admits to the polytechnic school at Delft, to the special course of the Indian service schools at Delft and Leyden, to the military school at Haarlem, and to the artillery course at Delft.

Industrial and Technical Schools.—The higher burgher schools are the only institutions comprised in the division of *middlebaar Onderwijs* which are intended for general education of the secondary type. The term, in fact, pertains to administrative rather than to scholastic relations and the great proportion of schools belonging to this department are industrial or technical in character. Hence they may be considered as forming part of the system of technical instruction. Many of these schools are burgher evening schools, others belong to special classes of technical schools. As regards control they may be public, i.e. established and maintained by communal authorities, or private. In any case they may receive State subsidies. The scope and variety of the schools of industrial arts are indicated by the following particulars of those maintained in two towns selected from a list of sixty-four institutions.

COMMUNE	NAME OF SCHOOL (ENGLISH EQUIVALENT)	NO. OF TEACHERS	NO. OF PUPILS
AMSTERDAM	(1) Evening drawing school for manual workers	27	554
	(2) Industrial school of the society of workers	13	106

	(4) Seminary for mechanics	21	175
	(5) Industrial school for young women	24	282
HERTOGENBOSCH	(1) Royal School for useful and fine arts	11	219

NETHERLANDS, EDUCATION IN

In all the schools of this class, drawing occupies the chief place; mathematics and the mother tongue come next in importance; other branches respond to local needs.

Of the more highly specialized schools, the Trade School (*Ambachtsschool*) at the Hague ('s Gravenhage) may be taken as a typical example. It was established in 1873 by an Association for the "Advancement of the Building Trades." It receives municipal support and is amply equipped for the accommodation and instruction of 300 boys. To the general subjects mentioned above, the Trades School adds special courses in wood and metal work and construction. The program covers three full years.

The specialized schools include eleven schools of navigation and ten for training fishermen. Commercial education is provided for by courses in the higher burgher schools and by special classes maintained by private societies, chambers of commerce, etc.

The schools of household industry for girls form one of the most important groups in this department. They number thirty, established by communes or by private associations and all but four subsidized by the State. Nineteen of the number are day schools; the remainder, generally, have both day and evening sessions. The duration of the course of training varies from one to three years; the range of fees is from 25 francs to 650 francs (\$5 to \$130) a year.

Included in this same administrative department are the communal institutions for the deaf-mute at Rotterdam and Groningen and one for the blind at Amsterdam, all subsidized by the State. The children committed to their charge receive their living and tuition gratuitously, excepting those whose parents are able to meet the expenses. "St. Michiel's Gestel" is an institution for the deaf-mute maintained by the Catholic Church, but receiving state appropriations.

The department of *middelbaar Onderwijs* includes also several schools of a professional character which do not, however, require the same order of preliminary training as the university faculties. Among these schools are: (1) The State Academy of Applied Arts at Rotterdam; (2) the state schools for the training of drawing teachers at Amsterdam and the Hague; (3) state training schools for midwives at Amsterdam and Rotterdam; (4) military and naval schools.

Agricultural Education.—The system of agricultural education in the Netherlands, which has attracted wide attention, forms a subdivision of this same department (*middelbaar Onderwijs*), although its transfer to the department of agriculture has been under consideration. In all matters relating to agricultural education the government is advised and assisted by the general Inspector of Secondary Education in charge of agricultural schools.

NETHERLANDS, EDUCATION IN

The system includes: (1) state establishments; (2) courses of instruction, theoretic and practical, maintained by the Provincial Agricultural and Horticultural societies, with the assistance of state subsidies. The state establishments are: (1) the Agricultural College at Wageningen; (2) the Agricultural and Horticultural winter schools; (3) the Veterinary College at Utrecht; (4) Instructors of Agriculture and Horticulture appointed by the government in the various provinces, to give instruction in their respective subjects.

The well known State Agricultural College at Wageningen consists of four sections: the Agricultural School, the Horticultural School, the High School, the High School for Agriculture and Forestry. An important feature of the institution is the thorough course in colonial agriculture intended for students who desire to go out as assistants or managers of sugar, coffee, tea, and other plantations in the colonies (Java), and who require, in addition, an elementary knowledge of colonial agriculture, laws, and customs. The college is controlled by a board consisting of the directors of the four sections. One member of the board is appointed by the Government as president with the title of *Hoofd-directeur* (Chief Director). He acts as the executive officer of the college. There are forty professors and teachers and an average of 250 pupils. The annual expenses of the college are about 1,100,000 fl. (\$142,200).

Higher Education.—The present system of higher education (*hooger Onderwijs*) is based upon the law of April 28, 1876, amended and modified by laws of May 7, 1878; June 28, 1881; June 15, 1883; and July 23, 1885. The institutions included in this department are either of public or private origin. The former are established and maintained by communes and the State, separately and conjointly; the latter may be subsidized from public funds. In accordance with the law of 1876, the public institutions are the gymnasia and Latin schools, the three state universities, and the communal university of Amsterdam; the denominational "seminaria" and other private institutions answer to the universities, but only the latter can confer academic degrees. The fundamental law established the principle of liberty in higher education; but all persons engaged in this service are subject to supervision by the educational authority. Foreigners must obtain authorization from the sovereign before they can be employed as teachers of the higher branches, in either public or private institutions.

The Gymnasia.—The classification of the gymnasia under the head of higher education is a peculiarity of the Netherlands system which follows historic precedents. The gymnasia have replaced in the modern system the classical schools which were preparatory to the universities. The higher burgher schools, classed as secondary, start at the same level as

NETHERLANDS, EDUCATION IN

NETHERLANDS, EDUCATION IN

the gymnasia and admit pupils at the same age, *i.e.* twelve years. To a certain extent the courses of the two classes of schools are parallel, as is shown by the programs. But the graduates of the higher burgher schools cannot enter the university faculties without at least a year's preparation in Latin and Greek. Authorities in Holland are divided in their opinion as to the wisdom of maintaining this distinction of degree between the burgher schools and the gymnasia, but so far the advocates of Latin and Greek as affording a higher order of intellectual discipline than the modern studies have prevailed.

The law requires that every community of over 20,000 inhabitants shall equip and maintain a gymnasium; other communities may take the same action. The supervision of each gymnasium devolves upon a communal council, styled College of Curators. The head

of a gymnasium, the Rector, and also the Co-Rector must possess the doctor's degree in classical philology; the professors must have either a university diploma or certificate from the State Examining Board. Appointments to these positions are made by the communal authorities; if the institution receives a state subsidy, the choice must be approved by the Minister of the Interior. The professors are present simply for their class instruction, and their salaries are regulated by the number of hours' instruction which they must give. The government inspectors report annually to the Minister of the Interior as to the condition of the public institutions of this order. Private gymnasia exist, also under authorization from the Minister, to whom they must send an annual report. The public gymnasia follow an official program, which is given below. The private institutions are independent in this respect.

CURRICULUM OF THE GYMNASIA

¹ Eight hours per week for part of year; five hours for remainder. Similarly as regards 0 and 3 in Class II.

² Extra for humanists.

³ Extra for "real" students.

Statistics. — There is a public gymnasium in each of the thirty principal cities of the kingdom and thirty-one additional private gymnasia. The former had in 1910 a total of 2250 students (1647 young men, 603 young women). The private gymnasia had in the same year 2048 students. Altogether there were 4298 students in this stage of higher education. The teaching force of the public institutions numbered 456 professors; of these 240 had the doctor's degree; fifty-five the title of docent; the remainder had certificates from state examining boards. The expenditure for the public gymnasia in 1910 amounted to 907,594.54 fl. (\$364,853) to which the State contributed 262,319 fl., or 28 per cent.

The Universities. — There are three state universities, Leyden, Utrecht, and Groningen, comprising each the five faculties of theology, law, medicine, science, letters, and philosophy. The internal administration of each university

is in charge of a college of curators, the members of which are commissioned by the sovereign. The university senate, which determines the scholastic arrangements, consists of members representing the several faculties, the choice being in each case sanctioned by the Minister of the Interior. The curators through their secretaries make detailed reports of the affairs of their respective institutions to the Minister of the Interior and submit each year an estimate of expenditures for the coming year. The Minister, in turn, presents the estimate to the legislature and disburses the appropriation allowed.

Professors in the state universities receive their appointment from the crown and may be suspended or dismissed by the Minister for incompetency or misdemeanors. On reaching the age of seventy, university professors are pensioned. The amount of pension is determined by the number of years of service, but

NETHERLANDS, EDUCATION IN

it may not exceed the sum of \$1206 per annum. Professors in the higher institutions belonging to the Catholic Church are also pensioned by the government.

STATISTICS OF THE UNIVERSITIES, 1910-1911

UNIVERSITY	No. OF STUDENTS	NUMBER OF PROFESSORS AND TEACHERS	EXPENDITURE	
			FL.	U. S. Equivalents
<i>State</i>				
Leyden	1195	78	1,119,260	\$482,102
Utrecht	1082	69	1,061,774	426,833
Groningen	551	51	817,519	328,043
<i>Communal</i>				
Amsterdam	1139	109	632,500	254,265
Total	3967	299	3,711,053	\$1,491,843

The faculty of medicine has the largest registration in all the universities. Leyden is particularly distinguished for law, which claims the greatest number of students after medicine. Utrecht leads in theology. The Doctor's diploma, which is conferred by the universities, carries mention of the Faculty in which the student has completed his studies.

The universities all have extensive libraries and are well equipped with laboratories and museums. Clinical facilities are afforded the students of medicine, in hospitals connected with the universities.

The provision for higher education is completed by a private university at Amsterdam, and about twenty-six denominational institutions in various places, some of which receive subsidies from the State. They are designated as seminaries, colleges, Latin schools, training schools. Their aim is generally the training of young men to serve as ministers in their respective churches and as teachers of higher branches.

The Polytechnic School.—The Polytechnic School at Delft affords the highest order of technical training for engineers, architects, and architectural engineers. The number of students in 1910 was 1235, including 705 not following a complete course. The faculty numbered fifty-four professors; there were also six private docents and eight assistant professors. The expenditure was 680,803 fl. (\$273,683). Every student of the polytechnic school pays \$80 in advance for the annual course, which entitles him to all the advantages of the school. Those taking elective studies pay only for the subjects chosen, at the rate of \$4 per annum for each study, with one recitation per week. For four or more recitations per week the fee is \$16 per annum for each study. The students who have taken the course of the polytechnic school at Delft, and wish to go to the East Indies as government officials, prepare themselves for such positions by taking a two or three years' course in the school at Leyden for the training of officials

NETHERLANDS, EDUCATION IN

in the East Indian service. Here they are taught the Java, Malay, and Boegine languages.

The instruction is under the general supervision of a college of curators, and the head master and teachers are appointed by the sovereign. The yearly program arranged by them must be submitted to the Minister of the Interior for his approval. The total expenditure for higher education in 1909 was 5,773,138.41 fl (\$2,320,802) derived as follows:—

	FL	PER CENT
State appropriation . . .	4,634,867.23	80.2
Province of North Holland . . .	10,000 00	0.3
Communes	1,128,271 18	19.5
	5,773,138.41	

Summary.—The system of education in the Netherlands is marked throughout by the harmonious action of somewhat incongruous elements combined in a rather loose organization. The effective working of the system is due: first, to the inspection service; second, to the high standard of the teaching force; third, to the examination tests which meet the student at every important stage of his progress. It is noticeable further that while the highest order of intellectual discipline is fostered, provision is made for training every aptitude which finds its exercise in the varied industries of modern life.

A. T. S. & C. H. P.

NETHERLANDS, COLONIES OF, EDUCATION IN THE.—With the exception of the British Empire of India, the colonial possessions of the Dutch in Malaysia form the greatest empire of dependent people in the world. This territory includes the major part of the two largest islands of the world, New Guinea and Borneo; the richest and most populous island, Java; and the famed and long-coveted "Spice Islands," the Moluccas. Four fifths of the entire Malay race inhabit these islands, and nearly three fourths of the entire number, or about 30,000,000, are on the island of Java, which is the seat of the Dutch administration. The smaller islands of the group are inhabited by black people. Arab settlements are found in important ports like Batavia, Samarang, Surabaya, and Makassar, or journeying as traders and proselyters. Through their religious faith, which they have communicated to the Malay race, they possess great influence over the entire population. The other important foreign element is the Chinese, who are settling in nearly all the towns of the archipelago, although restricted as to dwelling and place of business to certain quarters. They number about half a million, the majority of them residents of Java.

Until near the middle of the last century the education of the natives received little attention. But in 1848 after the Dutch States-General obtained control of the government of the colonies, an appropriation of 25,000 fl. was made for native education. In 1854, the *Regeerings Reglement* provided that the governor-general should establish schools for the native population, but the provision was vague and practically inoperative for many years. At last interest awoke; the Department of Education, Worship, and Industries was created in 1868, and about 1872 the organization of schools for the native people began in earnest. In 1884 a reaction set in and progress ceased.

But a reorganization of the education work was finally seen to be necessary, and in 1892 and 1893 there was sanctioned and put into effect a scheme of native instruction which had been proposed some years earlier by the director of education, Mr. W. P. Groeneveldt. Under this scheme two kinds of public instruction are maintained, one patterned upon the European system (*Europeesch Onderwijs*), the other native education (*Onderwijs voor Inlanders*).

European Schools.—Schools for the European population have long been provided. Under the new conditions they are more closely organized and are assured of government supervision and support. Their characteristic features are similar to those of the schools in the mother country. The public lower schools, in 1909, numbered 190 with 732 European teachers and 21,714 pupils. Of these 9120 were boys, and 7371 girls of European birth; 3693 were natives, 3190 being male; 1530 were Asiatic foreigners, largely Chinese, 1101 being male. There are also 40 private European lower schools aided by the government, with over 5000 pupils, mostly girls.

The rapid increase of native attendance in the European schools was one cause of the establishment of the native schools. Compared to the number of European or mixed European people for whom the former schools are created, the system must be regarded as exceedingly liberal. This population was reckoned a few years ago at 80,000, and its children were in public or private primary schools to the number of over 20,000, or more than 25 per cent of the corresponding population.

For secondary education of the European type, there are several schools, of which the most important is the Gymnasium William III at Batavia. This institution has a five years' course corresponding to that of the higher burgher schools in Holland, and in addition a special course preparing students for the civil service. The studies pertain to the languages, the geography, and ethnology of the Indies. Similar schools are founded at Surabaya and Samarang. The Queen Wilhelmina School is the name applied to a group of schools at Batavia giving secondary instruction of a technical character.

Native Schools.—The schools for Europeans are all open to natives, but they reach only a very small proportion of them. The scheme that was put into operation in 1892-1893 provided for a system of lower primary schools for natives only. These schools are of two classes: first and second. The latter offer a four years' course only in the common branches, instruction being given in the native dialect and Malay. The first-class lower school offers a six years' course and, besides instruction in the native dialect and Malay, gives three years' instruction in Dutch. The introduction of Dutch marks the return to a policy abandoned

twenty years ago. The language has proved indispensable as a basis for higher training, especially on administrative, technical, and professional lines, as well as for the intellectual development of the native. The authorities are convinced that the diffusion of the Dutch language among the peoples of their great Empire will be a political factor of the highest value; hence they have deliberately given up the former policy of discouraging its use in native education.

These graded schools will be located chiefly in the more populous places, but in 1906 a plan was adopted for establishing rural schools, *desa* schools, within reach of every hamlet; for it is admitted that until the rural population is taught to read, write, and keep accounts the mass will remain incapable of further advance. In accordance with this plan, schools are being rapidly established in all the islands. It is estimated that Java alone will require 30,000 *desa* schools. This development will call for an increased number of teachers from Holland and renewed efforts for the training of native teachers.

Normal Schools.—In the reaction of 1884 the number of normal schools for natives was reduced to four, situated respectively at Bandoeng and Probolinggo in Java, Fort de Kock in Sumatra, and at Amboina; a fifth school was added at Djokjakarta in 1897 and a sixth at Oenarang in the residency of Samarang in 1905. In these schools the government furnishes free instruction to students and provides them with furnished rooms and an allowance of 10 fl. (\$4 20) a month for food and clothing. The course of study in the normal schools is arranged for five years and comprises the Dutch language, Malay, and one other native tongue, arithmetic, geometry, land measuring and surveying, including leveling and waterways; geography, history of Netherlands-India, natural sciences, including elementary physics and meteorology; plant and animal life, writing in Arabic, in Javanese, or other native characters, and in Roman letters, music, and very thorough work in drawing, which is pursued for five years. In the fourth and fifth years instruction is given in pedagogy and school administration; the sixth and last year is devoted to general review and to practice teaching in a well-organized training school.

Schools for Native Officials.—Another important feature of the system is the establishment of training schools for native officials. The idea is not new, as schools of this class were created as early as 1878; but the entire character of the training has been changed, and to the four older schools, three new schools have been added since 1909. In several of the schools a normal department for training native teachers is included, and in the higher section the student pursues jurisprudence, public and administrative law of the Indies, political economy, land surveying, waterways, line and

map drawing. In 1909 a professional school intended to prepare native magistrates was opened at Batavia. It forms with the medical school at Batavia, which was reorganized in 1902, the nucleus of a native university.

Chinese Schools.—Special mention should be made of the Dutch-Chinese schools intended for the children of the extensive Chinese population by whom the practical value of education is fully realized as shown by their attendance upon the European schools. Such schools were organized in 1908 at Batavia, Samarang, Surabaya, and Makassar. In 1909 seven more were opened, at Menado (Celebes), Bandjermassin (Borneo), Singaraja (Bali), Padang (Sumatra), and at Malang, Surakarta, and Bandoeng, Java. These schools have the same organization and offer the same course as European lower schools.

Cost of Education.—The government expenditure for public schools in 1907 amounted to 2,678,353 fl. (\$502,252). The estimated cost for 1910 was 3,570,200 fl. (\$2,158,820), including subsidies to private schools. These sums do not cover the cost of construction of new buildings, which, except for *desa* schools, is borne by the State, and will amount in the next few years to large sums annually.

NEUCHÂTEL, UNIVERSITY OF, SWITZERLAND.

—Although the present university was only created in 1909, the municipal and cantonal authorities have for the last two centuries striven to provide an institution of higher learning. In 1659 a proposal was made to the town council to appoint instructors and professors to teach philosophy. In 1712 the council ordered four ministers to draw up a plan for the appointment of a professor of philosophy, and in 1731 Louis Bourget was appointed to this position. In 1737 a professor of literature was appointed. But there was as yet no definite institution. It was not until 1830 that serious efforts began to be made to establish an academy, inspired by the general movement to provide higher education in Switzerland. In 1838 it was proposed to found an academy to give courses preparatory to the universities and professional studies. In 1839 public lecture courses were given, and in 1841 the academy was established with seventeen professors in arts, science, and law, and additional chairs were provided in the next few years. Only the faculties of arts and science granted degrees. It is interesting to note that both Agassiz and Guyot (*qq.v.*) were members of the teaching staff at this time.

The academy, however, was closed in 1848, only to be reestablished on a more permanent footing in 1866, with the same three faculties, and gymnasiums or secondary school departments. The latter were organized into a cantonal gymnasium in 1872. In 1874 a faculty of theology was established, and 1883-1884 the faculty of law was empowered to grant degrees. In 1878 a course in French for foreigners was organized and later was converted into the *Séminaire de Français moderne pour Étrangers* (1892). In 1886 a building was erected for the academy, and in 1887 the first laboratories were added. But in spite of the rapid progress, the academy did not yet possess the same rank as other Swiss universities and still continued to give what properly belonged to the secondary schools. In 1894 a reorganization took place, and this deficiency was remedied to meet the standards generally prevailing in the country. In 1896 the laboratories were increased in number, and various collections were acquired. In 1909 the academy was raised to the rank of the university, with faculties of letters, science, theology, and law. One year's work is given for medical students. The *Séminaire* for foreign students has grown in popularity and attracts many foreigners. A *Diplôme pour l'Enseignement du Français moderne à l'Étranger* is given after a course of two semesters in the *Séminaire*. The enrollment in the summer semester of 1911 was 226 matriculated students and 76 auditors.

NEURASTHENIA. — According to Beard, the first to describe the disease, "neurasthenia is a chronic functional disease of the nervous system the basis of which is impoverishment of nervous tissues in excess of repair," and, according to Ziemssen, "it is a functional weakness of the nervous system varying from the slightest degree in certain localities to an entire loss of strength in the whole nervous system." No disease is as prevalent as neurasthenia, if with it we group its mental counterpart which is discussed under the title psychasthenia (*q.v.*). Although neurasthenia has been considered a typical American disease, it is not confined to those Americans who lead fast, energetic lives, but is found at all ages and among all civilized races.

Neurasthenia is a most insidious affection, since the symptoms resemble so much those which are to be found in normal children and adults as the result of ordinary work and fatigue. In fact, the symptoms in neurasthenia are principally those corresponding with fatigue and exhaustion. The individual

who suffers from neurasthenia has these symptoms, extending, however, over comparatively long periods, and it is because of the long-continued character of the symptoms that we consider them a disease.

The symptoms in neurasthenia are both subjective and objective, but it is upon the subjective ones that the diagnostician must depend for his chief information. The individual feels worried; he has a feeling of hopelessness or sometimes a simple and vague depression similar to that which is found in melancholia. Associated with these we find obsessions or fixed ideas. In connection with these subjective feelings we find an apparent lack of strength; there is less movement on the part of the individual and when movements are produced, they soon lead to weariness or fatigue; usually the appetite fails and there is a loss in weight. As an evidence of the lack of control of the nervous system, we find variations in the vasomotor system. The heart also is affected; we find cardiac palpitations and quickenings, sometimes a weakening of the force. In another field we find hyperesthesia, which is evidenced by restlessness or nervousness; the individuals are irritated by the slightest stimulation; parasthesias are frequent (feelings of itching and of burning, *e.g.* animals in abdomen, etc.). Headache is common, sometimes localized above the eyes, but most often at the occiput and extending down the spine along its entire length. We find on the motor side, a slowing in movement (retardation); the individual does not want to move; he takes a long time to start a particular movement, and when the movement is performed it is usually slow and of little force.

In the disease, fatigue is commonly noticed in the morning after sleep (morning tiredness). This is replaced after some hours with the ordinary feelings, so that the individual in the morning is less capable of carrying on work than in the latter portion of the day. Neurasthenia is especially common in women and children. At times when the demands upon the nervous system and the body are greatest, it is most likely to occur, *e.g.* at puberty. Although neurasthenia may arise in an otherwise healthy individual, it is usually to be found in individuals of nervous type, and in those upon whom hereditary influences are acting. The treatment of the disease is mainly that of rest.

Since many of these conditions start as the result of excessive stimulation and of excessive work during periods of strain, it will be understood that the condition is to be found commonly associated with the periods of growth and of great functional activity. At such times children should be protected as far as possible from excessive fatigue, and they should be permitted to carry on a minimum of school work; lessons should be short and easy and long periods of rest should be taken between

them. Such children must be kept out of doors as much as possible, and should be compelled to take a midday rest and go to bed early. The time lost in this way is really a gain because it prevents a general breakdown which may require a complete cessation of all activity for six months or a year. The permitting of such children to try for prizes in school is hygienically criminal. Children who show symptoms of fatigue beyond the normal from the work of the school day should be referred to the school physician for a careful examination. Their condition should be reported to the parents with a recommendation regarding the stopping of the school work.

The neurasthenic state is commonly found as a prodrome to many mental diseases. Whenever the symptoms are found they should be considered with suspicion, because if they are not neurasthenic they are generally the symptoms of disease of a grave character. It should be noted that the feeling of early weariness and of fatigue with depression are commonly early stages in a number of diseases, such as measles, scarlet fever, etc., and the reference by the teacher of such a pupil to the school physician will sometimes help to prevent an epidemic in her class or in the school.

NEUROLOGY. — See MEDICAL EDUCATION; PHYSIOLOGY.

NEURONE. — See NERVOUS SYSTEM.

NEUROSIS. — A term used to designate a nervous state. In combination, as psychoneurosis, to indicate a disease that has nervous, in contradiction to mental, symptoms in addition to the mental. Among the best known psycho-neuroses may be mentioned: epilepsy, (*q.v.*), hysteria (*q.v.*), and neurasthenia (*q.v.*).

S. I. F.

NEVADA, STATE OF. — Organized as a territory in 1861, and admitted to the Union as the 36th state in 1864. It is located in the Western Mountain Division, and has a land area of 109,821 square miles. In size it is about the same as the combined areas of the states of New York, Pennsylvania, New Jersey, and Maryland. For school administration the state is divided into 5 supervisory districts, and these in turn into 15 counties and about 325 school districts. In 1910 Nevada had a total population of 81,875, a school census (5–18 years) of 12,319, and a density of population of 0.7 per square mile. Though exceeded in size by but five states, Nevada has the smallest population and the smallest number of people to the square mile of any state in the Union.

Educational History. — The first territorial legislature in 1861 enacted as the first school

law one which contained all the provisions necessary for the beginning of a state system of schools, and laid down the fundamental outlines of the subsequent school system of the state. To a Territorial Superintendent of Public Instruction, to be elected in 1862, was given the general oversight of the educational system of the state. To assist him, an *ex officio* State Board of Education, composed of the Territorial Superintendent, Territorial Auditor, and Territorial Treasurer, was created. For each county a county superintendent of common schools was to be elected for two-year terms, to have general oversight of the schools of his county, and the usual administrative duties. He was to divide his county into school districts, for each of which three trustees were to be elected, to have general supervision of the schools of the district. They were to provide for the school, elect the teacher, take a school census, levy taxes, and visit and inspect the schools. A permanent state school fund, to be created from the sale of lands, was provided for, and fines were to be added to it. The system as thus early outlined has persisted in its main outlines until within the last ten years.

By the constitution of 1864, under which the territory was admitted to the Union, and which, with minor amendments, still stands, rather full provision was made for the future state school system. The legislature was enjoined "to promote intellectual, literary, scientific, mining, mechanical, agricultural, and moral improvement" and a uniform system of schools, with a term of six months as a minimum, was to be established in each school district of the state. A State Superintendent of Public Instruction was ordered to be elected; all school lands were declared to be an inviolable trust; sectarian aid was forbidden; a state university was to be established, and a state tax provided for it; and power to establish a normal school was granted. The first school law under the new constitution, enacted in 1865, carried these provisions into effect, and in addition created a State Board of Education, county superintendents for the counties, and county boards of examination, composed of the county superintendent and two persons appointed by him. The revisions of the school laws made in 1873, 1877, and 1879, made only minor changes, retaining the essential outlines of the system. The law of 1873 contained the first compulsory school law for the state. The State Teachers' Association was first organized in 1880.

The University of Nevada was created in 1873, to be located at Elko. A state normal school was also created in 1887, to be a department of the State University.

As a state, Nevada has had a slow and irregular growth, and this has influenced the development of the state's educational system. At the time of the admission of the state, the

school census, 6-18 years of age, was but 2,601. This increased slowly up to 1880, when the school census reached 10,592. After this a slow decrease in school census set in, owing to the decline in importance of the mining interests. After 1890 this decrease became a little more marked, the lowest figure, 8,996, being reached in 1898. Since 1903, through the opening of new mines of importance, the building of a number of new railway lines, and the development of agriculture through irrigation, the state has begun to increase in population more rapidly than at any time in its previous history. The number of school census children is now close to 12,500.

It is only since the recent increase in population and business that any real interest in educational legislation and development has been shown. During the period of decline and stagnation little was done, and some backward steps were taken. In 1887 the county superintendency and the county boards of examination were abolished, and the county district attorney was made *ex officio* county superintendent, but without salary. This virtually abolished all supervision. For the twenty-five years between 1880 and 1905, one State Superintendent after another recommended new legislation and asked for a new school code in vain. Minor changes were made from time to time, mostly relating to teachers' certificates, but no legislation of a fundamental or markedly progressive order was obtainable. It is practically only since 1907 that any marked progress has been made. State Teachers' Institutes were created in 1893, and state aid was granted to them. In 1895 a county high school law was enacted, but it was more than ten years before more than one school was established under this law. In 1903 the Virginia City School of Mines at Virginia City was created by the State, and placed under the control of the State Board of Education. In 1905 a public school library law was enacted.

In 1907 and 1909 important educational legislation was enacted and in 1911 a new School Code. These are embodied in the present system.

Present School System. — At the head of the system is an *ex officio* State Board of Education, consisting of the Governor, the President of the State University, and an elected State Superintendent of Public Instruction. The State Board of Education must meet at least twice yearly; prescribes the course of study to be followed in all the schools of the state; appoints all Deputy State Superintendents, on recommendation of the State Superintendent, and may similarly remove the same for cause; prepares all questions for the examination of teachers, and grants all teachers' certificates; determines the amount of money to be apportioned to the school district library funds; approves all apportionments to districts from the

State Emergency School Fund; appoints trustees for all free county libraries established; and acts as a Board of Trustees for the State School of Mines at Virginia City. The State Board also acts *ex officio* as a State Normal School Training Board, for all high schools offering normal training, and determines the qualifications for admission, establishes the course of study, grants the diplomas of graduation from the normal course, and makes rules and regulations for the management of such schools. Together with four others, principals or superintendents of schools, to be appointed by the Governor, the State Board unites to form a State Textbook Commission, which adopts all textbooks for the state for four-year periods, and contracts with publishers for the same.

The State Superintendent of Public Instruction is elected for four-year terms, and receives a salary of \$2,000 a year and an allowance of \$400 for traveling expenses. On his recommendation the State Board appoints a State Deputy Superintendent for each of the five supervisory districts into which the state is divided. They receive the same salary, a traveling allowance of from \$800 to \$1,200, and from \$400 to \$600 for office expenses. The State Superintendent is required to visit each county at least once each year; to prescribe forms; to make minor rules and regulations; to apportion the school funds to the districts; to approve all schoolhouse plans; to recommend the consolidation or enlargement of school districts; to make arrangements with California or Utah for the schooling, at state expense, of all deaf, dumb, or blind children in the state. He also must hold a State Teachers' Institute biennially, for which \$200 is appropriated by the state, and a district institute in each supervisory district in alternate years, for which \$150 is appropriated. He may also hold county institutes if the county commissioners approve, and will pay for the same. He must make a biennial report to the Governor, and edit and print the school laws.

Each deputy superintendent must be a resident of his district; must hold a high school teacher's certificate; must have had forty-five months' experience (nine in Nevada); and must devote his entire time to school supervision in Nevada. He must visit each school in his district at least twice yearly; examine all records; advise teachers; hold teachers' meetings; confer with trustees; examine all records and accounts of the district; and may suspend teachers or certificates for cause. He also acts as a deputy examiner at teachers' examinations, as a member of the State Board of Educational Examiners, and assists the State Board in preparing the state course of study for the schools. He attends meetings of the State Board, to advise as to affairs in his district, and acts for the State Superintendent in educational matters as directed.

There are no county school officials, except county boards of education in such counties as have voted to establish county high schools. Where this has been done, a county board of three is elected to manage the high school, under the supervision and direction of the State Superintendent and the State Board of Education, and their powers are about the same as those of district boards of school trustees. For each school district a board of three district school trustees is elected, one for two years and one for four years, at each biennial election. To these boards are given the power to employ teachers and to fix their salaries; to visit the schools; to enforce the course of study, and the adopted textbooks; to provide supplies and apparatus; to suspend and expel pupils; to enforce discipline and sanitary regulations; to provide for the schooling of indigents; to appoint a school census marshal each year; and to levy an annual district tax, up to 25 cents, for maintenance. If the district has 300 children, a kindergarten may be established; if 10 or more teachers, a superintendent may be employed; and if 1500 census children, a board of trustees, numbering 5, is to be elected. Vacancies, if not filled by election, are filled by appointment by the Deputy State Superintendent for the district.

School Support. — The state received the 16th and 36th sections of land for schools on its admission to the Union. In 1882 these lands, less a small amount sold, were exchanged with the government for 2,000,000 acres, to be located by the state on any free government land. The 500,000 acres of land granted to new states, the 5 per cent of public land sales, and all fines collected under the penal laws were also added to the permanent state school fund. This fund now amounts to approximately 2½ million of dollars, and the income, due to the small state school census, gives a large per capita apportionment. The salaries and expenses of the state office and deputies, the Emergency Fund, and the library fund, are all deducted before apportionment. In addition a state school tax of 10 cents on the \$100 (raised from 6 cents in 1911) is levied and added to the income from permanent funds. The distribution is made semi-annually to the counties on the basis of census children, 6-18 years of age. State money can be used only for teachers' salaries. A county tax of from 15 cents to 50 cents (average 25 cents) is also levied for contingent expenses, and a special district tax up to 25 cents may also be levied. All state and county school money is distributed to the districts within the county on the basis of 70 per cent on teachers (1 teacher calculated for every 30 census children, or fraction thereof) and 30 per cent on school census. Also a sum of from \$3 to \$5 per teacher and, in addition, from 5 cents to 10 cents per census child, as determined by the State Board of Education, is apportioned for school library purposes.

Teachers and Training. — The state has about 500 teachers, few of whom are paid less than \$70 per month, and salaries of \$100 and \$110 are common. Primary, grammar, and high school certificates are granted upon examination, though the primary certificate is fast passing out. The standards for these examinations are high. A State Board of Educational Examiners, composed of two from the State Board of Education, the five deputy state superintendents, and three others appointed by the State Superintendent, examine and grade all examination papers, and report to the State Board of Education, which then grants the certificates to teach. About 40 per cent of the teachers certificated for the state have been certificated on credentials (normal school, college, or state life diplomas) from other states. The state is relatively liberal in the matter of inter-state recognition of diplomas and credentials from other states. The state normal school is a department of the University of Nevada at Reno. The state has also recently begun the establishment of normal school classes in the high schools of the state for the training of teachers for the rural schools. This course must be thirty-six weeks long, the candidates for entrance must have a high school diploma or a primary teacher's certificate, and at graduation a three-years' certificate, not renewable, and good in only a one-room school, is granted.

Secondary Education — Within recent years there has been a marked gain in the number of high schools in the state. In 1890 there were 7 district high schools in the state; in 1900 there were 9 district high schools and 1 county high school; while in 1910 there were 11 district and 10 county high schools. The number of secondary school students has increased much faster than the number of secondary schools, and practically all of the schools now have a four-years' high school course. County high schools may be formed in any county by petition of one fourth of the voters, and a majority vote at an election. For these a county board of education of three is elected, who manage the school, under the direction of the State Board of Education, and determine the annual tax for the same. Such schools are open to any eighth-grade graduate in the county.

Educational Conditions. — Educational conditions in the state are now very good. The state system of supervision and inspection is efficient; there is a higher degree of centralization of authority than is found in many states; the school laws as a whole are good; and good provisions for the education of all children are made. Whenever five children can be found near enough together to maintain a school, the state sees to it that one is provided. The standards for teachers' certificates are higher and better than in most eastern states, the salaries paid are good, and the instruction

NEVADA, UNIVERSITY OF

offered is very good, considering the sparse population. There are a number of good high schools in the state. School libraries exist in each school district, and free textbooks may be provided by vote of the district. A six months' term of school is mandatory on all districts, and eight months if the funds at hand will provide it. The educational obligations of the state are well recognized in the large state and county taxation for education. Four cities and towns have city superintendents. Of the total population, 83.7 per cent live in rural districts. E. P. C.

NEVADA, UNIVERSITY OF, RENO,

NEV.—The State University and the only institution of higher learning in the state. It had its inception in the Federal land grants to Agricultural and Mechanical Colleges and Universities. There was no immediate demand for such a college, and it was not until 1873 that the State Legislature provided for its establishment at Elko. The University was opened in 1874 and existed for twelve years as a preparatory school with but few pupils. In 1886 the school moved to Reno, where after a lapse of one year it opened with the title University. Since then the growth has been gradual. At present the University comprises the following schools and colleges: college of arts and science, college of agriculture, including the schools of agriculture and of domestic science; the college of engineering, including the Mackay school of mines, the school of mechanical engineering, the school of civil engineering, and the college of education. The University campus covers an area of 49 acres, on a site which gives a commanding view of the city, valley, and mountains. The buildings number 15, all built by the state except the Mines Building, the gift of C. H. Mackay. The value of the University grounds and buildings is \$78,197 for grounds, \$528,476 for buildings, of which sum \$72,266 is for dormitories. The total receipts for the biennial period 1911 and 1912, according to the regular appropriations, exclusive of additions and buildings, will be \$412,180, of which sum \$220,000 is from Federal grants and \$192,130 from state appropriations. The enrollment of University students in 1912 was 223. The faculty numbers 48.

G. O.

NEVIN, JOHN WILLIAMSON (1803–1886).—College president; was graduated from Union College in 1821, and the Princeton Theological Seminary in 1826. He was professor at the Western Theological Seminary, Allegheny, Pa., 1820 to 1840, at the German Reformed Theological Seminary, Mercersburg, Pa., 1840 to 1853, and president of Franklin

NEW HAMPSHIRE, STATE OF

and Marshall College, 1866 to 1876. He was the author of several religious works.

NEW BRUNSWICK, UNIVERSITY OF, FREDERICTON, N.B.—Founded in 1800 as the College of New Brunswick. From 1805 the institution received annual grants from the Provincial Treasury, and from 1829 grants from the Crown. A Royal charter was obtained in 1828, incorporating the College as King's College. In 1845 all religious tests, except for the professor of theology, were abolished. After a commission of inquiry had reported, the University of New Brunswick was established in 1859 in place of the College. Four-year courses leading to the B.A. and B.Sc. degrees are offered to students, men and women, who have satisfactorily passed the entrance examinations. The courses are divided, according to the English system, into ordinary and honor courses. In the department of applied science courses are offered in the various branches of engineering and in forestry and lead to the degree of B.Sc. The University also confers all the usual higher degrees, including the B.C.L. and D.C.L. The University is affiliated with the universities of Oxford, Cambridge, and Dublin. The enrollment in 1910–1911 was 241.

NEW HAMPSHIRE, STATE OF.—Originally a part of Massachusetts, but organized as a separate territory in 1680. En-

tered the Federal Union in 1788 as one of the thirteen original states. It is located in the North Atlantic division, and has a land area of 9031 square miles. It is about one fifth the size of the state of New York, and about three fourths as large as Holland. For administrative purposes the state is divided into ten counties, but these have no educational significance. The counties are in turn divided into 231 towns and 26 originally independent school districts, and these are the educational administrative units of the state. In 1910 New Hampshire had a total population of 430,572, and a density of population of 47.7 per square mile.

Educational History.—The famous Massachusetts laws of 1642 and 1647 applied to New Hampshire, and continued to be in force for nearly a century. Dover, Exeter, and Hampton early provided for schools, and, what was unusual at that time, for girls as well as for boys. In 1680, the year of separation from Massachusetts, the first school law was passed, requiring the selectmen of the town to raise money, by assessment, for erecting and repairing houses of worship, parsonages, and schoolhouses, and for securing a teacher for the town. The old Massachusetts laws were continued in force, by common consent, and in 1719 the Massachusetts law of 1647 was definitely reenacted, but with the fine increased from £5 to £20. Two years later it was enacted that selectmen failing to enforce the law should be liable in their personal estates.

During the first fifty years of the independent existence of the territory, the Massachusetts policy of granting land for education was continued, and grants of a school lot in each township were made quite generally. In a few towns there are local funds which are the product of these grants.

Education in New Hampshire, as elsewhere in New England, declined during the eighteenth century. Little was done in the matter of schools, few grammar schools were in existence, fines were cut down, and laws were not enforced. The first state constitution of 1776 made no mention of education. New state constitutions were adopted in 1784 and 1792, and in each of these the general section relating to the encouragement of literature and learning, embodied in the Massachusetts constitution of 1780, was incorporated with only two words changed, and this has remained to the present as the sole constitutional requirements with reference to education.

In 1789 the first state law with reference to education was enacted, and all former laws were repealed. The rate of school tax which a town must raise was fixed for the first time, at the ratio of \$5 for every \$1 received from the state; an English Grammar school was ordered to be established in the smaller towns, and a Latin Grammar school in the larger

towns; and an examination of teachers, by ministers, college professors, or schoolmasters, was instituted for the first time. In 1791 the rate of town taxation was changed to $7\frac{1}{2}$ to 1; in 1795 to 35 to 1; in 1804 to 45 to 1; in 1806 to 75 to 1; in 1808 to 70 to 1; in 1813 to 90 to 1; and in 1840 to 100 to 1. By 1855 it had reached 200 to 1; by 1870, 350 to 1; and now stands at 750 to 1. This reveals how the burden of school support has gradually been shifted to the towns, until to-day the share carried by the state is very small. Only within recent years has the state begun to make special subsidies and equalization grants to overcome some of the defects of this method of school maintenance.

Up to the nineteenth century the town had been the unit in all school administration, but in 1805, following the lead of Massachusetts, the towns were empowered to subdivide into school districts. Town unity was partially retained for a time by the law of 1808, which directed that each town at its annual meeting should elect a school committee of three or more to visit and inspect the schools. Should the town fail to elect, the selectmen were to act as a school committee. In 1827 the number was fixed at three to five, and a district committee of one, to be chosen by the towns, was to be appointed to look after the schools in each district. To the town school committee was given the power to examine all teachers for the towns; to dismiss incompetent teachers and unruly pupils; to determine the textbooks to be used; to make an annual written report to the town meeting; and they were directed to visit and inspect the schools twice yearly; to encourage scholars to attend. The first statistics date from this time. In 1829 the town control was still further undermined by a law which authorized each school district to appoint its own district committee, of from one to three residents, and to give to this district committee power to select teachers, to provide board and fuel, and to supervise the school. In 1833 the culmination of the district system was reached in a law which permitted the towns, on account of expense, to dispense with the superintending town school committee, and thus leave the schools under district control. This condition of affairs continued for fifty years. A few of the cities escaped by organizing under special laws, Portsmouth in 1826 being the first. In 1857 two or more contiguous districts were authorized to unite. In 1870 permission to return to the town system of school administration was granted to the towns, and in 1885 the district system was abolished by legislative act, reducing at once the number of districts and district boards from 1890 to 275, and resulting in the immediate abandonment of 495 small schools.

In 1826 schoolmistresses were first recognized in the law, and in 1858 they were required to

meet the same standards as men for certification. In 1827 children whose parents did not provide books might be supplied by the school committee, and in 1833 the law directed school committees to provide destitute children with free books. In 1883 towns and districts were authorized to supply free textbooks to all. In 1829 the Literary Fund, established in 1821 by a tax on banks, for the endowment of a college, was ordered distributed among the towns, on the basis of state taxes paid, for the support of free public schools. In 1847 the basis of distribution was changed to school enrollment.

In 1830 the first high school was established at Portsmouth; in 1848 the third district of the town of Somersworth was permitted to establish one; and later in the same year any district was authorized by vote to establish and maintain a high school, and to elect a high school committee of from five to seven. In 1846 towns were permitted to contribute as much as 5 per cent of their school money for the aid of teachers' institutes, which were then first established by law. In 1851 this was reduced to 3 per cent, and in 1857 to 2 per cent, and in 1861 they were abolished as ineffective. In 1868 they were again ordered held, and state aid for them was granted, but in 1874 they were once more abolished. In 1883 they were again reestablished and have since remained. A State Teachers' Association was organized in 1854.

The beginnings of state school supervision were made in 1846, when a State School Commissioner, to be appointed by the Governor and Council, was authorized. He was to spend twenty weeks each year among the counties, encouraging education; was to collect educational statistics; and was to make an annual report to the General Council. In 1850 the office was abolished, and county commissioners, one for each county, took his place as supervisory officers, and together they constituted an *ex officio* State Board of Education. Despite efforts to reestablish the state office, this system of county supervision continued until 1867, when the county school commissioners were legislated out of office, and the office of State Superintendent of Public Instruction was established. The new Superintendent was to be appointed by the Governor for two-year terms, and the State Superintendent, Governor, and Council together were to constitute an *ex officio* State Board of Education. In 1874 the State Board was abolished, but the State Superintendent has been continued to the present time.

In 1848 the first law relating to truancy was enacted, and all children working in factories were required to have had three months' schooling each year. In 1870 all children eight to fourteen years of age were required to attend school for twelve weeks each year, six weeks of which must be consecutive. The

law was further amended in 1901 to make it practically conform with the truancy and child labor laws of the other New England states. In 1866 the State Agricultural College was established as a department of Dartmouth College, but in 1891 the connection with Dartmouth was severed, and the College was moved to Durham and given an independent status. In 1870 a state normal school was established and located at Plymouth. In 1895 the State Superintendent was authorized to institute a system of examinations for state teachers' certificates. In 1895 the employment of a superintendent by two or more towns was authorized, and in 1899 supervisory unions of two or more towns for the purpose were provided for, and state grants for the partial payment of the salary of the superintendent were begun. In 1899 annual state appropriations were begun, from the state treasury, to be used in equalizing the local tax rate for schools in those towns where the burden was excessive, and in making state grants in aid of supervision. In 1901 towns not maintaining a high school were required to pay the tuition of their pupils in high schools elsewhere, and state aid for the purpose, to those whose tax rate exceeded a certain rate, was begun. These grants have since been materially increased.

Present School System.—At the head of the school system is a Superintendent of Public Instruction, appointed by the Governor for a two-year term. To him is given general supervision and oversight of the educational interests of the state. He is authorized by law to prescribe the forms of blanks, reports, and registers to be used in the state; to receive and preserve all school documents; to investigate educational conditions in the state; to visit the schools and lecture in the towns; to hold at least one institute in each county each year; to audit the expenses for such, and to draw on the state treasury to pay for the same out of the income of the institute fund; to recommend to school boards desirable books for instruction in temperance physiology and hygiene; to prepare a biennial report of his work and to issue biennially the school laws of the state. He also approves high schools for tuition grants and supervisory unions for supervisory grants; holds examinations for and grants state certificates to teachers; acts *ex officio* as one of the Board of Trustees for the state normal school, and as regent (secretary) of the State Board of Medical Examiners.

Below the state are 231 towns and twenty-six independently organized districts. Since 1885 each town has been constituted a single school district, except that the independent school districts in existence at that time were permitted to continue, unless they voluntarily gave up their existence and united with the town. Each district is required to hold an

annual school meeting for the election of officers, hearing the annual reports and voting funds. Women may vote at these meetings. The meeting each year elects a moderator, clerk, one or more auditors to examine all books and accounts, and one member of a school board of three, to serve for a three years' term. Any district, by vote in annual meetings, may require the trustees to employ a superintendent of schools, and two or more towns having twenty to sixty teachers may unite to form a supervisory union for the same purpose. If a high school is maintained, there may also be a high school board of three, six, or nine, as determined by vote, or the high school district may be consolidated with the district or town and placed under the control of the school board.

Districts (or towns) may raise money for current expenses, buildings, repairs, equipment, and debts; may borrow four fifths of the money necessary to erect a building, payable in five years' time; may vote to maintain a high school, or unite with another town in doing so, or contract with a high school, academy, or seminary to educate their high school pupils for them; may determine the conditions of admission to the schools; and must raise by local taxation a sum not less than \$750 for every \$1 of money received from the public treasury.

The district or town school boards are to select, employ, and for cause dismiss all teachers; must provide a sufficient number of schools, and may expend 25 per cent of the money raised for the conveyance of pupils; must include temperance physiology and hygiene and the constitutions of the United States and of New Hampshire among the required studies in the schools; must provide free textbooks for pupils, and fix prices at which parents wishing to provide their own may buy them; are supposed to hold examinations for teachers in June or July of each year, issuing one-year local certificates to those found satisfactory; must visit the schools twice each term; must appoint truant officers for one-year periods, and fix their compensation, and must prosecute violations of truancy or child labor laws; and must make annual reports to the selectmen of the town and to the State Superintendent of Public Instruction. If a superintendent of schools is employed, most of the duties devolving on district boards are delegated to him. On a petition of 5 per cent of the voters in any district of 5000 inhabitants or over, evening schools must be established for the education of children over fourteen.

School Support.—The state received no land for education from the general government, and the Surplus Revenue distributed in 1837 was spent for general state purposes. The state has never established a permanent common school fund. The proceeds of some state lands, ordered to be sold in 1867, now known

as the Institute Fund, constitutes the only permanent state fund, and the annual income from this is used to defray the expenses of teachers' institutes. The Literary Fund is the proceeds of an annual tax levied on bank, building and loan, and trust company deposits of persons not resident in the state, and at present produces about \$40,000 each year. This is distributed to the towns on the basis of the number of children enrolled in the schools for at least two weeks each year, and is worth about sixty cents per pupil. Any districts existing within the towns receive their proportion on the basis of valuation. The state also makes grants annually to assist poor towns in paying the tuition of high school pupils; for assistance in paying the salaries of superintendents (the state paying one half the salary); and for giving extra aid to towns having less than 3500 total population, and whose valuation is less than \$7000 per child in average daily attendance. This last is granted to the towns in direct proportion to the average daily attendance, and in inverse proportion to the valuation per child. All other school expenses are paid by the towns and districts, and the amount so raised averages about one half more than that required to be raised.

Of all school revenues raised during the last year for which statistics are available, 7 per cent came from state sources, 88.2 per cent came from local taxation, and 4.8 per cent came from local funds, tuition fees, gifts, excess of dog taxes, town treasury payments, and other miscellaneous sources. The inequalities under this system, due to inequalities in wealth, are large, and these inequalities the state has attempted to equalize in part by a wise system of state aid.

Educational Conditions.—Of the total population of 1910, 22.4 per cent were of foreign birth. But few of the native-born population are illiterate; but for the foreign born about one fifth are so classed. Of the foreign born, 50 per cent were French Canadians, 16 per cent were English Canadians, and 90 per cent were from Canada or the British Isles. The percentage of children five to eighteen years of age in the total population is lower than in any other state of the Union except Nevada. There are practically no negroes in the state, the whites constituting 99.8 per cent of the total population; 40.8 per cent of the people live in rural districts, and 42 per cent in cities of over 8000 inhabitants. The attendance and child labor laws are good. Truant officers must be appointed by each town and district, and they may be directed to inspect factories. Three state inspectors also assist in the enforcement of the truancy and labor laws. No child under twelve can work at all in any manufacturing establishment; and no child under sixteen during the hours the schools are in session with-

out an age and schooling certificate, showing that he can read and write the English language. If over sixteen and unable to read and write, such pupils must attend evening schools, up to twenty-one, unless excused on account of health. All children under sixteen must attend school unless employed. Attendance at a private school is accepted only when the school is taught in the English language, and has been inspected and approved as equal in instruction to the public schools of the town, and when attendance is looked after as required by law.

There are no statutory school studies, aside from temperance-physiology and hygiene, humane education, and the constitutions of the United States and of New Hampshire. About 60 per cent of the schools of the state are classed as graded schools. Four cities maintain evening schools, and about twenty-five supervisory unions have been formed. The laws for the location of schoolhouses, change of property from one district to another, power granted to the annual district meeting, etc., show the same oversensitiveness for the feelings of communities and for a small and aggrieved minority that characterizes much of the New England school legislation.

Teachers and Training.—Teachers' certificates are of two kinds. The local certificates, granted by local school boards, supposedly on an examination in the subjects which the teacher is to teach, but in practice usually without an examination, and valid for one year and only in the district, constitute one kind, and are held by most of the teachers of the state.

The other kind is granted on the basis of a written examination, given under the direction of the State Superintendent, and to graduates of the normal school. This form is required of all district superintendents, and is valid anywhere in the state. The local district examinations are so easy or so nearly extinct that there is little to impel teachers to attempt these state tests.

For the training of new teachers, the state maintains the normal schools at Plymouth and Keene, and four cities (Concord, Manchester, Nashua, and Portsmouth) maintain city training schools. For the training of teachers in service the State Superintendent is directed to hold at least one teachers' institute in each county each year, or to appoint the principal of the normal school to do so, to audit the expenses, and to draw on the state treasury to pay the same from the income of the Institute Fund. From twenty to twenty-five one-day teachers' institutes are held each year, with about one half of the teachers in attendance. An institute for superintendents is also held, and an eight weeks' summer institute at the normal school. Attendance at a teachers' institute is optional, though teachers may close their schools and attend

one day each term, and receive pay for attendance. The last report of the State Superintendent shows that from thirty-nine towns no teacher has attended an institute in two years, from nine towns in four years, and from six towns in six years. Many other towns have been represented by one, two, or three teachers only.

Secondary Education.—Seventy-two public high schools were reported in 1910 as existing in the state. A high school, once established, cannot be changed in location or discontinued except by order of the Superior Court for the town, and on petition of the school board. To be approved, a high school must maintain at least one four-year course, embracing such subjects as are required for entrance to colleges, and including the constitution of the United States and of New Hampshire. In special cases, the State Superintendent may approve partial courses for partial state aid. A number of academics and seminaries have been approved for the attendance of pupils at public expense.

Higher and Special Education.—The New Hampshire College of Agriculture and Mechanical Arts at Durham is the only higher institution supported by the state. This institution offers instruction in general science, agriculture, and engineering, and is the only college in the state open to women. Dartmouth College (*q.v.*), at Hanover, a nonsectarian institution opened in 1769, and St. Anselm's College, at Manchester, a Roman Catholic institution opened in 1893, are two additional higher institutions, for men only. The State Industrial (Reform) School, at Manchester, is the only special institution maintained by the state.

NEW HARMONY.—See PESTALOZZIAN MOVEMENT IN THE UNITED STATES; OWEN, ROBERT.

NEW JERSEY, STATE OF.—One of the thirteen original states. It is located in the North Atlantic Division, and has a land area of 7514 square miles. It is about one seventh the size of the state of New York, and about one half as large as Switzerland. For administrative purposes the state is divided into

twenty-one counties, and these in turn into 458 cities, independent boroughs, and school townships. In 1910 New Jersey had a population of 2,537,167, and a density of population of 333.7 per square mile. Excepting Rhode Island and Massachusetts, it is the most densely populated state in the Union.

Educational History.—Situating near the center of the different colonies, the development of education in New Jersey was the product of a number of influences. The Dutch crossed from New Amsterdam, the English came from Connecticut, Scotch and Scotch-Irish Presbyterians came from Great Britain, the Swedes settled along the Delaware, and the Quakers came over from Pennsylvania. The population was thus a compound of these various elements. The first school was established by the Dutch at Bergen in 1661 or 1662, and in 1673 it was ordered that all the inhabitants be compelled "to pay their share toward the support of the preceptor and schoolmaster," thus making it a publicly supported school. There seems to have been much difficulty in enforcing this, however, as the people "obstinately refused to pay their quota." After the transfer of New Amsterdam to the English in 1664, the English soon extended their control over northern New Jersey, and the English language and English methods ruled in the schools. See section on early education in New York, STATE OF.

As early as 1665 an English colony had settled at Elizabeth, and in the founding of the neighboring town of Woodbridge in 1669, 100 acres of land were set apart for education. A school was established here in 1689. In 1666 the town of Newark was settled by two migrations from the towns of Milford, Branford, and Guilford, Connecticut, and ten years later a schoolmaster was appointed by Newark "to do his faithful, honest, and true endeavor to teach the children or servants of those as have subscribed, the reading and writing of English, and also arithmetick, if they desire it; as much as they are capable to learn and he capable to teach them within the compass of this year." Other early settlements were made at Middletown, Freehold, Shrewsbury, Piscataway, and Perth Amboy.

In 1693, and in amended form in 1695, the East Jersey Assembly, at Perth Amboy, enacted "An Act for establishing schoolmasters in this province," which authorized the inhabitants of any town, under warrant of a justice of the peace, to meet and choose three men of the town "to make a rate for the salary and maintenance of a schoolmaster." The consent of a majority was to make the rate a binding one on all. What proportion of the towns established schools under the provisions of this law we do not know.

In 1682 the Assembly of West Jersey granted the island of Matinicum, located in the Delaware River, being about 300 acres in extent, to the town of Burlington, "from henceforth and forever hereafter for educational purposes." The early Quaker settlers of this western province were a well-educated people. With them the schoolhouse was the general accompaniment of the house of worship. Schools and meeting houses were accordingly soon established by them in their towns, and the schoolmaster was generally appointed by the church session, instead of the civil authority, as was the case in early Massachusetts history. See MASSACHUSETTS, STATE OF; DISTRICT SYSTEM.

In 1702 the two provinces of East and West Jersey were united and placed under the Governor of the colony of New York. For the following seventy-five years, up to the Revolutionary War, during all of which time this arrangement continued, there was almost no legislation relating to education. (See NEW YORK, STATE OF, EDUCATIONAL HISTORY.) Schools were still maintained in many of the colonies, but they were of a voluntary and private rather than a public nature. A subscription elementary school was maintained in a small number of the towns; a few private grammar schools (of which the Log College of Wm. Tennent, at Nashamany, was a type) were provided; and the Friends, in Yearly Meeting, in 1746 and again in 1787, laid down directions concerning education. In their resolutions they declared that "the education of our youth in piety and virtue, and giving them useful learning under the tuition of religious, prudent persons," was extremely desirable, and they therefore urged that the Society's meetings "be excited to proper exertions for the institution and support of schools." The main acts of educational importance in New Jersey during the first three fourths of the eighteenth century were the establishment of the College of New Jersey, now Princeton University, in 1746; the founding of Rutgers College, at New Brunswick, in 1766; the confirming in 1769 of the 100 acres for schools, granted a century earlier to Woodbridge township by George III; and the appointment of a Board of Trustees for the management of the lands, to insure their application to the original purpose of the grant. The War of the Revolution put an end to English control and to the early colonial schools.

New Jersey adopted a state constitution in 1776, but this contained no mention of education. The Federal Constitution was ratified in 1787, but no new state constitution was adopted at that time. A new interest in education seems to have been awakened after the establishment of the new Federal Government, and many academies were founded in different parts of the state. It was not until 1816, however, that any official

state action was taken. In this year an act was passed which made the beginnings of a state school fund for the support of schools. An annual state appropriation of \$15,000 was made to start the fund. This was to be invested in United States 6 per cent bonds, and the interest was to be added to the principal and reinvested. In 1818 the chief state officers were made trustees for the growing fund; in 1824 this was changed to an annual addition of one tenth of the income from state taxes; and, in 1829 it was further provided that taxes from banking, insurance, and other corporations should be added to the fund. In 1820 the townships (or towns, as they were frequently called) were first authorized to raise money by taxation for school purposes, though until 1838, excepting the one year from 1830 to 1831, money raised for support was limited to the education of "such poor children as are paupers." In 1828 townships were further permitted to raise money, by vote at township meetings, for the erection and repair of school buildings.

An extensive investigation was made in 1828, which showed that one third of the school children of the state were growing up without any chance of an education. The law of 1829, the first to provide any organized plan for a school system for the state, was the result of this investigation. Each township was to elect a school committee who should divide the township into school districts; examine and license teachers; visit the schools, at least every six months; and make a report to the annual school meeting and to the Governor of the state. Three trustees for the districts, a district school census, and annual district meetings were provided for, and a state appropriation of \$20,000 annually for support was made. This latter was to be distributed to the counties on taxables, and to the districts on census. The next year, however, this newly established school system was abolished, largely through the influence of the friends of private and church schools. By the laws of 1830 and 1831 the old limitation of support to the education of poor children was reestablished, the distribution of the state appropriation was so changed as to include all private and parochial schools, as well as the township schools; and both district lines and the examination of teachers were abolished. It was not until 1838 that these reactionary laws were finally repealed. In that year a convention of the friends of public schools free from all denominational control, issued an address to the people, and the result was such a popular manifestation that the legislature repealed the law of 1831 and enacted a new one, which contained many of the features of the law of 1829. The religious orders were still aided; the licensing of teachers was made optional; the mention of pauper children as the only ones entitled to state aid was finally

abandoned; and the annual state appropriation was increased to \$30,000.

In 1844 a new constitution was adopted for the state, and in this, under the head of legislative powers, a paragraph was inserted which declared the school fund to be a perpetual fund, and the income to be appropriated only for the support of public schools. In 1875 this was further amended by inserting the word "free" between "public" and "schools," and adding a mandatory clause requiring the legislature "to provide for the maintenance and support of a thorough and efficient system of free public schools for the instruction of all children in the state between the ages of five and eighteen years." These remain the only constitutional provisions relating to education which the state has ever adopted.

In 1845 the beginnings of state supervision were made by the passage of a law permitting the appointment of a State Superintendent of Public Schools for the counties of Essex and Passaic, with liberty to the other counties to avail themselves of this state supervision. The following year a new school law was enacted which extended state supervision to the entire state; provided for local supervision by townships, by supplanting the township school committees by a town school superintendent; made the licensing of teachers obligatory; and required the townships to levy a local tax double the amount of any state school funds received. From 1846 to 1866 the State Superintendent was elected by the Trustees of the School Fund, but since 1866 he has been elected by the State Board of Education. Only four different men have served the state as State Superintendent during the forty-five years from 1866 to 1911. In 1848 the townships were permitted to use the interest on the Surplus Revenue for schools; in 1851 the state appropriation was increased to \$40,000, and a limit of \$3 per census child placed on district taxation; in 1854 teachers' institutes were first established, and a state appropriation of \$100 for each was made; in 1855 the first state normal school was established; and in 1858 the state appropriation was further increased to \$80,000. Here matters rested until after the Civil War.

In 1866 an *ex officio* State Board of Education, consisting of the Governor and state officers, was created, and the State Superintendent was changed to be its executive officer and secretary. In the following year a new school law was enacted, which practically created the modern system, and has formed the basis for laws since that time. The State Board of Education was reconstructed and given enlarged powers; county superintendents were created to supersede the township superintendents; state, county, and city boards of examination were provided for, and a certificate from one of the three

required of all teachers; the various district trustees in each township were constituted a township board of trustees; corporal punishment was forbidden; the state appropriation was increased to \$100,000 annually; and the limitation of \$3 per census child on district taxation was removed. In 1871 the rate bill (*q.v.*) was finally abandoned and the schools made entirely free. To accomplish this and to provide a nine months' term as required, a state tax of two mills was imposed, in addition to the appropriation, and additional township taxes were permitted, when necessary, to meet the demands of the law. In 1874 a compulsory education law was enacted, and in 1876 all state aid to private or parochial schools was finally forbidden.

In 1881 the first of a long series of constructive legislative acts was passed, whereby any district, raising by subscription or taxation a sum of not less than \$3000 a year and not over \$5000 for industrial training, was to receive an equal amount from the state, for the same purpose. In 1887 the same provisions were extended to districts raising from \$500 to \$5000 a year for manual training. In 1888 the school districts of any township were permitted to consolidate and to provide a township form of organization; and in 1894 transportation was permitted. The same year the district system, except for cities and boroughs, was abolished by law, and a form of the townships-county system was instituted. In 1894 scientific temperance was required in all schools, and a free textbook law enacted; and in 1896 the State Board of Education ordered a uniform course of study and uniform standards of promotion to be instituted by counties. In 1896 a teachers' retirement law was passed. In 1898 the State Board of Education established a "Bureau of Information for Teachers and School Officers," which it has since conducted.

Beginning with 1900, constructive legislation has been even more marked than during the previous decade. In that year the State Board appointed a supervising architect, and began the state supervision of all schoolhouse plans; and annual grants of \$600, to any district or township which appointed a superintendent of schools or a supervising principal, were begun. County superintendents were required to hold a state teachers' certificate, and their salaries were changed from a school census to a teacher employed (\$7 per teacher, in 1902 increased to \$8) basis, and materially increased; the normal school course was extended and improved; a more liberal policy in the recognition of diplomas and training in place of examinations was begun; and kindergarten classes were first authorized. In 1901, after ten years of investigation of the results of the school census, the state school tax was increased to two and three fourths mills, and the basis of apportionment changed from school census to a combination of teachers

and attendance. In 1903 all school districts were made corporations, independent of the local municipal governments, thus erecting the school system as a state rather than as a local undertaking. In 1904 the State Board of Education appointed a high school inspector, and began the inspecting and grading of high schools. In 1905 county superintendents were given a uniform salary of \$2000, and schooling for all children in the state until twenty years of age was made possible. In 1906 an additional source of state taxation for education was provided, which has doubled the state appropriation for schools, in the form of a railway tax on all main-stem and first-class railway property in the state. With this increase in funds, the appropriation for teachers in high schools was doubled, and a grant of \$25 of state aid per pupil was made to all districts sending pupils to schools elsewhere. A new state normal school was also established at Montclair in this same year. In 1909 a teachers' tenure act was passed, giving indefinite tenure to teachers after three years of continuous employment. In 1911 an important law reconstructed the State Board of Education, abolished the office of State Superintendent of Public Instruction and created instead the office of Commissioner of Education, with Assistant Commissioners, as outlined below. All city boards of education were made appointive by the mayor, instead of in part elective; provision was made for the instruction of sub-normal and defective children; city teachers' certificates were abolished; and tenure and the civil service act were extended to all employees of school departments.

Present School System. — The New Jersey system, as it exists at present, is a somewhat closely organized state school system. At the head is a State Board of Education of eight members, appointed by the Governor with the concurrence of the Senate, and for eight-year terms (after the first appointments). The general duties of this State Board are to make rules and regulations for the carrying out of the school laws, for the management of teachers' institutes, and for the examination and certification of all teachers; to appoint all county superintendents, and to approve their expense accounts; to prescribe a uniform system of bookkeeping; to hold hearings; to appoint a supervising principal for union schools, and to consolidate or discontinue high schools, when deemed desirable; and to determine tuition rates and compel districts to receive pupils. In its power to make such rules and regulations as from time to time are found necessary, or deemed important in carrying out the provisions of the school laws, the State Board is enabled to determine many details in the administration of the school system of the state which in nearly all other states require legislation.

The State Board also acts as a Board of Trustees for the two state normal schools, for the New Jersey School for the Deaf, for the State Manual Training and Industrial School for Colored Youth, for the summer school for instruction in manual training, agriculture, and home economics, and the Farnum Preparatory School. The Board approves all books and apparatus to be bought for schools; approves the course of instruction and grants of money to schools offering courses in manual training or industrial work; and approves the courses of instruction in high schools, and inspects and grades the schools.

Probably, the most important function of the State Board of Education is the selection and appointment of a Commissioner of Education for the state, who acts as the executive officer of the Board. He receives a salary of \$10,000 a year, is appointed for five-year terms, and no residence restrictions are to be insisted upon in making the appointment. With the advice and consent of the State Board, he appoints four Assistant Commissioners at \$4500 salary, and the State Board also appoints an Inspector of Buildings and an Inspector of Accounts, each at \$2000, the first of whom approves all school plans and buildings, and the other inspects the accounts of the district officers. Three of the Assistant Commissioners act as inspectors of high schools, of elementary schools, and of industrial and agricultural education, and the fourth Assistant Commissioner hears all controversies and decides all appeals on school law questions. The specified duties of the Commissioner of Education are to ascertain whether the system of education provided is thorough and efficient; to prescribe a minimum course of study for both elementary and high schools; to prescribe rules for the promotion of pupils in the elementary schools, and to prescribe uniform examinations for eighth-grade graduation and admission to the high schools, which shall be open alike to public and private school pupils; to prescribe the Binet, or other tests, for use in the schools; to withhold funds from any school district not obeying the law; to provide instructors and lecturers for teachers' institutes; to hold an annual convention of all city and county superintendents, to make a monthly report to the State Board of Education, and an annual report for the Board. The State Commissioner acts *ex officio* as a Trustee of the State School Fund, and apportions the income to the counties; as a member of the State Board of Examiners; and as a member of the Board of Trustees for the Teachers' Retirement Fund.

For each of the twenty-one counties of the state the State Board of Education appoints a county superintendent of schools. The appointment is for a three-year term, the appointee must hold a state teacher's certificate,

and a uniform salary of \$2000 is paid to each, by the state, with an added allowance for expenses and clerical assistance. Each county superintendent has the general supervision of the schools of his county, cities under city superintendents excepted; is to visit and examine all schools, and to note the condition of the school property; is to advise and counsel with the boards of education within the county; may recommend, with reference to courses of instruction, methods, management, or buildings; appoints members of Boards of Education, when the people fail to elect; carries out the instructions of the state office; and makes an annual report to the State School Commissioner.

Each township is a school district, but any city, incorporated town, or borough may be organized as a separate school district. For each, a board of education of nine members is elected or appointed for three-year terms, one third going out of office annually. In all cities the board is appointed by the mayor (since 1911), and in all townships, towns, or boroughs the members are elected by ballot at an annual school election. The general powers of all such Boards include the power to employ and dismiss teachers; to make rules and regulations, not inconsistent with law or the rules and regulations of the State Board; to purchase, lease, and sell school-houses, and to condemn land for school purposes; to select and provide textbooks and supplies; to admit and expel pupils; and to make an annual report to the county superintendent. Township, town, and borough boards may also appoint a supervising principal, or superintendent, or unite with other such boards to do so, and all such boards must meet together, semiannually, with the county superintendent for the consideration of school matters. Two or more townships, towns, or boroughs may hold an election and vote to consolidate their schools, the board of education for the consolidated district having the same powers as the boards of the districts voting to unite. Similarly, boards of education in two or more adjacent school districts may unite to provide a union graded school.

Boards of education in cities must appoint a city superintendent, who has the right of a seat and speech in the meetings of the board, but no vote. City boards of education are also to appoint a business manager to have general charge of all matters relating to school buildings, and a secretary, who acts as a secretary and general accountant for the school system. Each head of a department appoints all of his subordinates. The board may also appoint, on nomination of the superintendent, such assistant superintendents as it may desire, and fixes the salaries and tenure of all employees. The board must print an annual report and make an annual report to the State Commissioner. A board of school estimate,

consisting of two members of the city board of education, two members of the city council, and the mayor of the city, determines the rate of city school taxes, which the council must levy, regardless of any charter restrictions.

School Support.—The school fund, begun in 1816, now amounts to about 4½ millions of dollars, and produces an income fixed by law at \$200,000. Any deficit is made up from the state treasury. The surplus revenue of 1837 was distributed to the counties and in part used up, but the interest on the total received is a charge for which each county must provide. The income from this source is about \$28,000 a year, and is used for schools. The chief support of the schools comes from a state tax of 2½ mills on all property, and from state railroad and canal taxes. This property tax is materially reduced each year by an appropriation, made by the legislature from the state treasury. Approximately 5 million dollars came from this source in 1910, and 2½ millions of this came from state railway taxes. Excepting 10 per cent of the 2½ mills state tax, which is set aside as a reserve fund, all state money is distributed to the counties on the basis of their taxable wealth. The 10 per cent is also distributed to the counties by the State Board, in such a manner as in their judgment best equalizes the inequalities of the distribution of the other 90 per cent.

Within each county the county superintendent apportions the school money to the different townships, towns, boroughs, and cities on the following bases:—

For each superintendent or supervising principal	\$600
For each assistant superintendent or supervising principal	400
For each teacher in a four-years' high school	400
For each teacher in a three-years' high school	300
For each teacher in all other kinds of schools	200
For each temporary teacher, for 4 months or more	80
For each evening school teacher	80
For each pupil attending high school in another district	25
For each pupil attending elementary school in another district	5
For each teacher dispensed with by transportation	200
For transportation to other district, if school not close, 75 per cent cost.	

All that remains after setting aside the above sums is apportioned equally on the basis of attendance, and at the rate of so much per pupil per day. These apportionments provide for a very good equalization of burdens and advantages within the different counties. Any township, town, or borough may vote additional sums for maintenance, and city boards of school estimate may levy additional sums, as needed. All state money can be used only for salaries, fuel, transportation, and the payment of tuition.

In addition to the above, the state makes a number of annual grants, each one of which must be preceded by the district concerned raising an equal sum. These annual grants are as follows:—

For school district libraries, \$20 the first year, \$10 yearly thereafter.

For teachers' libraries, \$100 the first year; \$50 yearly thereafter.

For manual or industrial training, from \$250 to \$5000.

For evening schools for foreigners, over 14 years old, up to \$5000.

Educational Conditions.—The conditions surrounding education in New Jersey may be said to be good. The state is densely populated. Only about one fourth of the population live outside of cities and towns of 2500 inhabitants and over, while one half of the total population live in cities of over 25,000 inhabitants. Three and one half per cent of the total population is negro, and 25.9 per cent is foreign born; 75.2 per cent live under urban conditions. The state is largely a manufacturing one, with many residential towns and extensive country estates.

The school system is one of the better centralized state systems, and the county is an important unit. The school laws make good provision for education. A nine-months' school term is required of all districts. Suitable accommodations and proper sanitary appliances must be provided by each district. All schoolhouse plans must be approved by the State Board of Education, and may be obtained from the state free. Definite standards and requirements as to school buildings are insisted upon. Any board may establish kindergartens, evening schools for pupils over 12 years of age, or for foreign born over 14 years; and any city of over 10,000 inhabitants may establish schools for workmen. Every board may employ a medical inspector. Vaccination is insisted upon, unless excused for certain statutory reasons, and the cost of this is to be paid by the school authorities, if the parents are unable to pay. Textbooks and supplies must be provided free in all schools. All children in the state must be provided with free education, between the ages of 5 and 20, and no exclusion from any school may be made on the basis of race, religion, or color. Free high school education must be provided for all children applying for it, within or without the district. The kindergarten has made great headway since its adoption as a part of the state school system, and 30 per cent of the children now have been kindergarten trained. Corporal punishment is forbidden in all schools, public and private. All state prisons must provide schools offering an elementary school course, to be approved by the State Board of Education. All children, 7 to 17 years of age, must attend school regularly. Pupils over 15, properly employed, and who have completed the grammar school course, may be excused, but if under 17 and unemployed, they must attend a high school. Truant officers and parental schools are provided for, and any county may establish a school for the detention of juvenile offenders. A State Board of Children's Guardians exists

for the care of indigent, helpless, dependent, abandoned, friendless, and poor children.

Teachers and Training.—A State Board of Examiners, consisting of the Commissioner of Education, the principals of the normal schools, and one other appointed by the State Board of Education, examines candidates and grants all state teachers' certificates. Diplomas of a university or college may be accepted in any examination in lieu of subjects covered. Three grades of state certificates are issued. Normal school and teachers' college diplomas, and state certificates from other states are recognized. A Bureau of Information for Teachers and School Officers, serving as a state teachers' bureau, is maintained by the State Board of Education.

Each county may have a county board of examiners, consisting of the county superintendent and three teachers appointed by him, for one-year terms, who then conduct three examinations yearly, for the three grades of county certificates issued. The examination and certification of teachers is done under rules and regulations of the State Board, and little is specified in the law. In 1911 the city boards of examination and city certification were abolished. All city school teachers must now hold a county or state certificate. All superintendents and assistant superintendents of schools, both county and city, must hold state teachers' certificates. Seventy-five per cent of the teachers in the state have had normal school or college training, or have advanced by study and hold a state teacher's certificate. For the training of future teachers, the state maintains two state normal schools, at Trenton (1855) and Montclair (1906), and the cities of Elizabeth, Jersey City, Newark, and Paterson also maintain city normal schools. Each Board of Education may make its own rules and regulations regarding the employment and tenure of its teachers, though, theoretically, teachers are supposed to have indefinite tenure after three years of service in any one position. There is a state salary schedule, fixing reasonably good salaries for all positions, which may be adopted by any city by a referendum vote. A State Teachers' Retirement Fund has been created, by which teachers paying 2 per cent (in some cases as high as 3 per cent) of their annual salaries may be pensioned after 20 years of service, if incapacitated. A city may retire any teacher on half pay after 35 years of service, 20 of which have been in the city.

Secondary Education.—Of the 458 school districts of all kinds in the state, 109 had approved four-years high schools, at the date of the last report, and 51 other districts had partial high schools. Most of these schools are large and well equipped. The state inspection and approval is more thorough than is found in most states: Any private high school may be inspected, on application, and

if approved may be registered, which enables its graduates to be admitted to the state normal schools on the same terms as pupils from approved public high schools.

Higher and Special Education.—New Jersey maintains no state university, the two state normal schools being the culmination of the public school system of the state. The agricultural college grant is given to Rutgers College (*q.v.*), where the state maintains 120 state scholarships, and pays Rutgers \$15,000 annually for the purpose. These are competitive, and county superintendents conduct examinations for them, each county being allowed as many appointments as it has members in the state legislature.

The following private institutions provide for the collegiate instruction within the state, though all are for men except the last, which is coeducational:—

INSTITUTION	LOCATION	OPENED	CONTROL	FOR
Princeton University	Princeton	1746	Nonsect.	Men
Rutgers College	New Brunswick	1766	Reformed	Men
Seton Hall College	South Orange	1856	R. C.	Men
Sievens Institute of Technology	Hoboken	1871	Nonsect.	Men
St. Peter's College	Jersey City	1878	R. C.	Men
Upsala College	Kenilworth	1893	Luth.	Both sexes

As institutions for the education of special classes, the state maintains the New Jersey School for the Deaf, at Trenton; the New Jersey Training School for Feeble-Minded Girls and Boys at Vineland; the State Home for the Care and Training of Feeble-Minded Women at Vineland; the State (reformatory) Home for Boys at Rahway; the State (reformatory) Home for Girls at Trenton; and the State (secondary) Manual Training and Industrial School for Colored Youths, at Bordentown.

NEW LANARK.—See OWEN, ROBERT.

NEW MEXICO COLLEGE OF AGRICULTURE AND MECHANICAL ARTS, MESILLA PARK, N. MEX.—A coeducational institution established by the legislative as-

sembly of New Mexico in 1889 under the provisions of the Morrill Act of 1862. The nucleus of the College which was opened in 1890 was the Las Cruces College, organized in 1889. The College receives the usual federal appropriations for agricultural and mechanical institutions and an annual state appropriation. The following courses are given: agriculture, mechanical engineering, electrical engineering, civil engineering, household economics, commerce, general science. In addition, college preparatory and industrial courses in agriculture, mechanics, domestic science, and business of high school grade are provided. Musical and preparatory departments are also maintained. The enrollment in all departments in 1911-1912 was 372, of whom 66 were in the college courses. The entrance requirements for the college courses which lead to the B.S. degree are fifteen units of high school work.

NEW MEXICO, STATE OF. — Ceded to the United States by Mexico in 1848, and organized as a territory in 1850. In 1863 the territory of Arizona was organized from the western half of New Mexico territory. In 1912 New Mexico was admitted to the Union as the forty-seventh state. It is located in the Western Division, and has a land area of 122,503 square miles. In size it is twice as large as the six New England states combined, and about the same size as the British Isles. For administrative purposes the state is divided into 27 counties, and these in turn into school districts. In 1910 New Mexico had a total population of 327,301, and a density of population of 27 persons per square mile.

Educational History. — When the United States acquired New Mexico in 1848 the people spoke only the Spanish language, and there were few, if any, schools in the territory. The Mexican government had made small annual appropriations for schools in six of the towns, but these grants ceased with the passing of sovereignty. Such schools as were provided for the next decade, at least, were provided by the Catholic Church. In 1859 St. Michael's College, a school established by the Christian Brothers (*g.v.*), was opened in Santa Fé.

The first mention of education by the legislative assembly of the territory is in a memorial to Congress in 1853, asking for a penitentiary, roads to the state, and "the creation and support of public schools throughout the territory." Congress taking no action, the legislature memorialized Congress again in the following year, appealing for adequate assistance in starting a school system. The memorial recites that there are but one or two schools in the territory, and these private; that the reserved sixteenth section lands are of no value; and that there are 25,000 adults in the territory (seven eighths of the population) who cannot read or write.

The legislature asked for an annual appropriation, which was not made. The first school law, passed at the session of 1855-1856, provided for schools to be supported by taxation, for county boards of education, schools in each county, compulsory education, and fixed the salaries for teachers. A referendum was allowed in four counties, which later rejected the law by a vote of 5053 to 37. The next year the law itself was repealed by the legislature, and the taxes collected were returned to the people who had paid them. In 1857 the territorial legislature again memorialized Congress, this time asking for a grant of \$500,000 to establish a school fund, and offering to pledge the school lands as collateral security, but again without avail. In 1860 a new "Act providing means for the education of children" was passed. This law required the justices of the peace of each plaza to act *ex officio* as school trustees, to employ teachers, and to provide a six-months' term of school, and also provided for salaries, compulsory education, and free schools. Very few, if any, schools seem to have been organized under this law. In 1863 an *ex officio* Territorial Board of Education was created, with the Bishop of New Mexico as one member, with authority to make rules and regulations and to require schools to be established in each county. The Governor was also to appoint a Territorial Superintendent of Schools, to supervise the schools, and to report to the Territorial Board and to the Governor. The Territorial treasurer was made custodian of all school monies. In 1863 another memorial, asking for money to establish schools, was sent to Congress with a statement that 60 per cent of the people could not read or write, and that "there is not a public common school in the Territory." This and subsequent memorials met the same fate as the preceding. In 1867 a new law made the probate judges *ex officio* county superintendents of schools, and the justices of the peace *ex officio* school superintendents of their election precincts, each of which was constituted a school district. Two persons in each county were to be appointed to solicit subscriptions from the wealthy, and all fines for the violation of the school law were to be used for schools.

In 1872 laws which really first organized the school system were passed. By these a state tax of $\frac{1}{4}$ of 1 per cent was levied for school purposes, — the first taxation for education, — and a poll tax for schools was specified. It was further provided that if any county had a surplus of \$500 or more in its treasury, after paying all current expenses, the surplus should be used for schools. A board of supervisors and directors of schools was to be elected in each county, and they, together with the probate judge, were to have the establishment and management of the schools of the county. A number of counties took advantage of this

law, and proceeded to the organization of public schools. In 1874 the law was amended to require the making of full annual reports by the county boards to the Territorial Superintendent; to provide for the election of school officers; and the Territorial Superintendent of Public Schools was also designated as *ex officio* Territorial Librarian at a salary of \$150 a year. In 1876 a number of fines were designated to be used for the support of schools. By 1875 reports show that there were 138 schools in the territory, with 147 teachers employed. Most of the schools were still for boys only, and were in part religious schools. A bill providing for a nonsectarian school system was considered, but defeated in 1875. The above legislation practically established the public school system in the territory, and no further legislation of any importance occurred until 1884.

In 1884 the old laws were repealed, and a new school law was enacted creating the school district in place of the election precinct, and establishing the district system of management. County superintendencies were created, and the school studies specified. In this condition the educational organization remained until 1891. In 1891 a new school law was passed, which not only inaugurated the present school system, but may be said to have created a real school system for the first time. Previous to 1891 "there were not 50 public schools in the territory under the control of competent teachers, and in which the English language was taught," while in 1893 the Superintendent reports 519 such schools. Church schools and academies supplied much of the instruction. The New-West Educational Commission also did valuable work in providing schools, both before and for some time after the territory really began the work of education. By the law of 1891 a new Territorial Board of Education was created, and a new Territorial Superintendent of Public Instruction superseded the old Territorial Superintendent of Schools. Instruction in English was made obligatory, and all teachers were required to hold county teachers' certificates, obtained on examination before a county board of examiners. In addition, the College of Agriculture and Mechanical Arts was established in 1888; the University of New Mexico, and the New Mexico School of Mines were established in 1889; the State Deaf and Dumb Asylum in 1891; two state normal schools in 1893; and the State Military Institute in 1895. In 1893 teachers' institutes and in 1897 territorial normal institutes were authorized. In 1897 the annual appointment of indigent students to the state institutions was begun.

In 1901 the legislature further revised and amended the school laws. The Territorial Board of Education was enlarged; the preparation of all questions for the examination

of teachers in the territory was given to the Board; the attendance of teachers on county institutes was made compulsory; teachers in districts where Spanish is spoken were required to be able to speak both Spanish and English; distinctions based on race or nationality were forbidden; vaccination was required; and increased taxation was provided. Between 1901 and 1909 a large amount of minor legislation was enacted, but little that changed the form of administration. A Spanish-American normal school, for the education of Spanish-speaking young men and women as teachers, was also established in 1909. As the state had been expecting statehood for some time, but little educational legislation was enacted during the last few years under the territorial government.

Territorial School System.—The territorial school system as it existed at the close of the territorial period, in 1911, was as follows: There was a Territorial Board of Education, consisting of the Governor and the Superintendent of Public Instruction, as president and secretary respectively, *ex officio*, and seven additional members, appointed by the Governor. Five of the seven were to be selected from the heads of the territorial educational institutions, the president of St. Michael's College of Santa Fé, and the city superintendents of the four largest cities in the territory. One other member was to be a county superintendent of schools. The remaining member was not to be a teacher. This Board apportioned the territorial school fund; specified the duties of county superintendents; prepared all questions for the examination of teachers; selected the uniform textbooks for the schools; and had control of the county institutes. The Territorial Superintendent of Public Instruction was appointed by the Governor, with the consent of the council, for two-year terms. He visited the various counties in the interest of education; conducted teachers' institutes; outlined the courses of study for the territory; and acted as secretary of the Board of Education. His salary was \$3000 per year.

For each county there was a county superintendent of schools, elected by the people for two-year terms. His salary was based on a combination of the number of schoolrooms in session for at least three months each year, and upon the amount collected in his county from the three-mill territorial tax, but with a maximum of \$1200 per year. He had charge of the interests of education in his county; apportioned the school fund to the school districts of his county; visited the schools; and looked after the enforcement of the school laws. For each school district there were three school directors, one elected each year for a three-year term. It was their duty to care for the school property of the district, to provide teachers, and to perform the com-

mon duties of a school trustee. Cities and towns were permitted to organize as such and to elect boards of education of two from each ward, who were to organize, supervise, and maintain a graded system of schools, and levy needed special taxes for maintaining the same.

The Enabling Act.—In 1898 Congress granted the territory the 16th and 32d sections, and 500,000 acres of land for its public institutions, and in 1908 further granted the right to locate indemnity lands. By 1908 one fourth of these lands were under lease, and beginning to bring in some income for the support of public schools. In 1910 Congress passed an Enabling Act for the admission of New Mexico as a state, and granted to the state sections 2, 16, 32, and 36 in each congressional township, as a permanent endowment fund for common schools,—a total of 8,618,736 acres. Lands in eastern New Mexico were not to be sold for less than \$5 per acre, in western New Mexico for less than \$3 per acre, and lands capable of irrigation for less than \$25 per acre. The 5-per-cent fund (see NATIONAL GOVERNMENT AND EDUCATION) was also given for common schools; 1,160,000 acres additional were also given to the state for the endowment of its higher educational institutions, and for public and charitable purposes, and on the same conditions. A permanent common school fund of from thirty-five to forty-five millions of dollars should eventually be built up from these grants, and from twelve to fifteen millions additional from the grants for higher educational institutions.

A state constitution was framed by a constitutional convention in 1910, and ratified by the people in 1911. The educational system provided for the new state in this constitution does not differ materially from the territorial school system. Women are eligible for school offices and may vote at school elections on the same terms as men, unless a majority of the voters file a protest in writing. A uniform system of public schools, sufficient for and open to all children of school age, must be established and maintained and a five-month school term is made mandatory for all schools. Textbooks are to be uniform throughout the state, and not to be changed oftener than once in six years. The permanent school fund is specified, state and local taxation are permitted, and the income from the permanent school fund and from taxation is to be apportioned to the school districts on school census. A sufficient reserve fund is, however, to be withheld to provide all school districts levying the maximum local tax sufficient funds to provide the required five-month term of school. State educational institutions of all kinds must forever remain under the exclusive control of the state, and no school funds may ever be used in aid of any sectarian, denominational, or private school. A compulsory education law and a child labor law are to be

enacted by the legislature. A State Board of Education, of seven members, is to have the control, direction, and management of all public schools, under such regulations as may be provided by law. The Governor and State Superintendent are to be *ex officio* members, and the other five are to be appointed by the Governor, with the consent of the Senate. Of the five one must be the head of some state educational institution, one a county superintendent, and a third a person engaged in educational work. Other school officers, subordinate to the State Board of Education, and either the district or other form of organization, are to be provided for by the legislature. Normal schools are made mandatory. No religious test is ever to be required of any teacher or student in any public school or state institution. Children of Spanish descent are never to be denied admission to any public school or educational institution, or to be classified in separate schools. All territorial educational institutions previously established are confirmed as state institutions, and for each a bipartisan Board of five Regents is to be appointed by the Governor. A state department of agriculture, under the control of the Regents of the College of Agriculture and Mechanical Arts, is to be created. All school section lands, not contiguous to other state lands, are not to be sold within ten years for less than \$10 an acre.

Educational Conditions.—Considering the difficulties under which the new state has labored, the schools maintained are very good. The seven incorporated cities and thirteen additional towns maintain schools which will compare favorably with those in other parts of the country. Eighty-five and eight tenths per cent of the population live in country districts, and in these reasonably good schools are provided. The state has a large number of persons of Indian and Mexican birth, or descent, and these greatly complicate the educational problem. An effort is being made to require that all normal-trained teachers are able to speak Spanish, and the ability to speak both Spanish and English is required by law for many districts. The school laws and a guidebook for school directors are still printed in Spanish, as well as in English, editions. Two Indian mission and twelve Government Indian schools were maintained in the territory in 1910. With the development of the public schools, both the Protestant and Catholic Indian schools have decreased much in numbers and in importance, although twenty such schools were still maintained in 1910 by five different denominations. High schools are being developed in the towns and cities, there being eleven four-year high schools and seven shorter-course schools in 1910, as against six and two nine years before.

Teachers and Training.—About 1600 teachers are required at present for the different public schools of the territory. A

state professional certificate is held by 6 per cent of the teachers, while the remainder hold one of the three grades of county certificates, or are teaching on permits. For the training of future teachers the state maintains three state normal schools at Silver City, Las Vegas, and El Rito, but both the attendance and number of graduates of these schools are small. A teachers' institute of at least two weeks' duration must be held by county superintendents annually, and all instructors must hold certificates granted by the Territorial Board of Education.

Higher and Special Education. — The state maintains the following higher and special educational institutions: University of New Mexico at Albuquerque; the New Mexico College of Agriculture and Mechanical Arts at Mesilla Park; the New Mexico School of Mines at Socorro; the New Mexico Military Institute, a boarding school of secondary grade, at Roswell; the New Mexico Asylum for the Deaf and Dumb at Santa Fé; the New Mexico Institution for the Blind at Alamogordo; the New Mexico Orphan Childrens' Home at Belen; the New Mexico Orphans' Home and Industrial School at Santa Fé; and the New Mexico Reform School at Springer. There are no private or denominational institutions of collegiate rank in the state.

NEW MEXICO, UNIVERSITY OF, ALBUQUERQUE, MEX. — Established by an act of the Legislature. The first department organized was a normal school which opened in 1892. In the same year the preparatory school was opened and the commercial school added in 1893. The Hadley Laboratory was erected in 1899. The university at present consists of a college of letters and arts, a college of science and engineering, a commercial school, a school of education, a school of music, a sub-freshman division and the summer school. The plant consists of seven buildings. Owing to the extremely favorable situation of the university, many students have come from time to time from distant states and countries.

The university received a grant of 11,000 acres of public land and the grant of the saline lands of the territory for university purposes. By the enabling Act of 1911, a further grant of 200,000 acres was made to the institution and the saline grant was withdrawn from entry. The present appropriation granted by the territory to the university is \$32,000. The

institution is coeducational, the number of students of each sex being about the same. The registration for 1910-1911 was 137.

NEW ORLEANS EXPOSITION. — See INTERNATIONAL CONGRESSES OF EDUCATION.

NEW ORLEANS UNIVERSITY, NEW ORLEANS, LA. — An institution founded in 1872 for the education of the colored youth. It is under the auspices of the Methodist Episcopal church and is one of the twenty-two schools maintained by the Freedman's Aid Society of the church. In 1878 the first class was graduated from the College of Liberal Arts. The number completing this course has been small. In 1887 the first class was graduated from the professional teachers' course. From the beginning this has supplied a great need, for the demand for trained teachers is practically unlimited. In 1889 the medical college was opened, and schools of pharmacy and nurse training are now maintained. In 1898 a hospital in connection with the professional schools was opened. Classes in Biblical instruction have been maintained with more or less permanency since 1890. The University now owns property worth \$150,000 and has an enrollment of between five and six hundred pupils. Its curriculum embraces the entire range of studies from the grades up through the normal, college preparatory, and college courses, in addition to the professional courses above mentioned.

C. M. M.

NEW SCHOOLS. — A term applied to a series of schools which have been established within the last twenty years in many European countries and are organized so far as possible in accordance with results of recent studies in child life. They all are characterized by great freedom from the national administrative authorities, by greater attention to the individuality of pupils, and by their location in the country, they are close to nature. Among these schools may be mentioned Abbotsholme and Bedales (*qq.v.*) in England, *École des Roches* (*q.v.*) in France, and the *Deutsche Landerziehungsheime* (*q.v.*), established originally in Germany by Dr. Lietz and now copied in Switzerland, Russia, and Denmark.

NEW TESTAMENT, PEDAGOGY OF THE. — It would be idle to seek in the New

Testament a technical pedagogy, although it is doubtful whether any literature of similar origin and character recognizes more practically the importance of instruction. The new religion of Christianity was educational in that it strove to socialize ideals of conduct and to train the Christian communities in the significance of these ideals. This general educational tendency is apparent in the New Testament, the most important literary fruit of the life of the churches.

Education in New Testament Times. — This is treated in detail in the article on JEWISH EDUCATION. It is enough to recall the following points: (a) By the time the New Testament books were written there were Jewish schools throughout Palestine either in connection with the synagogues or independent therefrom (cf. Josephus, *Ag. Ap.* 2:16). Whether or not these schools existed in the smaller towns or in fact in any of the towns outside of Jerusalem during the lifetime of Jesus himself is uncertain, but that Jewish youths received formal training in their national laws and customs is plain from the statements of Josephus and from references in the Mishnah. (b) In the Hellenistic world educational methods were well developed, though higher forms of instruction were largely in the hands of independent philosophers like Epictetus. (c) The age was not without a general pedagogical philosophy, as is clear from our knowledge of the Greek and Roman literature (cf. Plato's *Republic*) as well as from the writings of Justin Martyr and other early Christian authors. (d) Memoriter methods were highly developed. This fact is characteristic of all periods in which textbooks are not readily available. Oriental training emphasizes verbal memory and extended compositions are preserved unwritten by the students of successive generations. The Jewish scholars furnished no exception to this rule, the Mishnah, for example, not being reduced to writing for centuries. This habit enabled the early church to preserve the memorabilia of Jesus in a quasi-systematic way for approximately a generation before they were reduced to writing and the various streams of tradition were combined into our present gospels.

The Method of Jesus. — Jesus has universally been regarded as one of the world's great teachers, but such an estimate has been based on the substance rather than upon the methods of his instruction. It would be incorrect to think of Jesus as a teacher in the sense of a schoolmaster who gave systematized instruction in the elements of culture. He was more of a preacher and conversationalist than a teacher, and his teaching was exclusively ethical and religious. Thus he would naturally be classed with the rabbi and the itinerant philosopher. Unlike Paul, however, he seems never to have received definite rabbinical

training (cf. Jn. 7:15). The fact that by occupation he was an artisan, very probably a carpenter (cf. Mk. 6:3), did not detract from his dignity as a teacher, for all the rabbis had some trade. That he was not uneducated is to be inferred from the fact that he was able to read the Hebrew Scriptures (Lk. 4:17-20), although Hebrew was no longer the current language. It is further significant that, so far as we have any record, there was no opposition to his being called "Rabbi," although in his case the term may have been little more than a polite term of address.

Beyond these general conclusions, however, particularly regarding the chronology and language of his sayings, it is impossible to speak with absolute precision. Painsstaking criticism alone will enable us to allow for the apostolic reworking of Jesus' teaching, and even after the most methodical handling, we find ourselves still facing questions of details. Yet thanks to modern scholarship we are able to reproduce with great probability his teaching as a whole and to estimate the methods which Jesus as an instinctive and natural teacher adopted. In general his methods were those of other moral teachers of Judaism, although he differed widely from them in technique and spirit. In his method — or more truly, his manner of teaching — we can discern the following characteristics —

His teaching was occasional and conversational rather than formal and systematic — The Sermon on the Mount as at present arranged in both Matthew and Luke has, it is true, a considerable unity of structure, particularly in its Matthean form. It may be questioned, however, whether this unity is due to the compiler of his sayings or to Jesus himself. Probably a middle view is preferable, to the effect that Jesus at some time set forth in orderly fashion his position on certain points of Jewish ethics and that gradually other sayings of his were nucleated about this material into what appears now as a considerable discourse. But the arrangement of the sayings of Jesus was certainly very unlike the discussions attributed by Plato to Socrates. Even less were they the product of a literary process. To a considerable extent they were the outgrowth of controversy and generally were the apparently unpremeditated expression of his convictions regarding definite matters proposed to him by either friend or enemy. Yet it would be unfair to say that, while his teachings were thus occasional rather than systematized, they lack unity either in point of view or in substance. Their spontaneity and almost anecdotal quality give them much of their charm and efficiency without detracting from the unity of impression due to their radiating from a central conviction. However various the circumstances which occasioned their utterance, the sayings of Jesus are astonishingly easy to

group schematically, for his thought was lucid and consistent. The repetition of important truths not only was necessitated by this occasional method, but serves to give the student the perspective of his thought, at least as it appeared to his immediate hearers, for repetition is one of the most common modes of emphasis in earnest instruction.

His teaching was analogical and poetic rather than literal and scientific.—Speaking generally, Jesus has left us no sayings dealing with the world of nature except as illustrative of moral and religious truths. His central positions are expressed more literally than are their amplifications, but his method is not that of scientific exposition. Compare only his teaching as to virtue with that of Aristotle's *Ethics*. Judaism had developed a literary form of power and beauty in its Wisdom literature. This equivalent of the Greek poetical composition had a definiteness of structure marked by parallelism and strophic arrangement. Such teaching was highly figurative as well as epigrammatic and may be illustrated by the sayings of Jesus concerning the supremacy of the eternal life over all physical goods (Mk. 9 : 47 sq.). The use of this literary form was in thorough accord with the anti-legalistic, inspiring spirit of Jesus himself.

Another type of such analogical teaching is the parable. Such a form was not unknown to the rabbis, but in its use by Jesus it reached an incomparable literary beauty. As a pedagogical device a parable is a story of facts, judged to be real or at least not impossible by the speaker and hearers, which is used to enforce or illustrate a spiritual truth. It is generally introduced by some word of comparison such as "like." This form of teaching is of particular value in bringing unaccustomed truths home to men in that it appeals at once to their experiences. It further serves, as Jesus himself seems to say (Mk. 4 : 11), to lodge a truth in the mind of one's auditors even before it is fully understood. The analogy is thus made germinal conviction,—and its use thus appears an element of a consciously adopted method of teaching. This method of instruction Jesus seems to have used almost exclusively during the few months of relatively peaceful instruction after the Galileans began to regard him with favor, and while he was beginning to unfold his constructive ideals.

Other forms of his analogical teaching are similes and the apocalyptic imagery of his day. On this latter point it is not necessary to dwell as criticism shows that Jesus used the form only rarely, and then as a point of contact with his Jewish hearers.

His teaching was progressive and to some extent cumulative.—If one will compare the teachings of Jesus as he took up his work with those which he uttered in the latter part of his ministry, it will be apparent that he passed from the heralding of the message that the

Kingdom of God was immediately to come to the less dramatic exposition of the bearing of his central position of God's Fatherhood upon social relations as well as of the indispensable virtues of love and forgiveness. In this transition a genuine progress can be seen from the appeal to the preconceptions of his unlettered audience to the inculcation of his characteristic positions. Its justification in large measure lay in the fact that he had gathered about him a group of disciples who were increasingly sympathetic with his own aims, and, despite the persistence of their earlier naïve expectations, were ready to accept his teachings as authoritative. In the fourth Gospel (Jn. 16 : 12) we have preserved a distinct tradition of a saying of Jesus to the effect that he had practiced self-restraint in his teaching and that he must leave the completion of his instruction to the work of the Holy Spirit in the hearts of his disciples. Such progress made possible the most valuable of the contributions of Jesus to religious thought. He might have left others, if only the disciples had been capable of abandoning more completely their inherited prejudices. In a number of instances Jesus speaks of the disciples' slowness and dullness shown in grasping his real meaning. Like any other teacher, Jesus found himself handicapped by the incapacity of those whom he instructed: e.g. by the fear of his own disciples to ask questions concerning even so vital a matter as his announcement of his approaching death. Thanks to this timidity on the part of his disciples, the world has never known precisely how Jesus himself interpreted his death.

His teaching was conditioned by the degree of intimacy which existed between Him and those whom He instructed.—On the outside of his circle of friends were the Pharisees. To them Jesus stood in unalterable and fundamental hostility. He never undertook to instruct them. On the contrary, in order to exhibit distinctly the difference between their legalism and his own belief in religious freedom, he criticized them mercilessly and endeavored to make himself a friend of those who were morally discontented. But within the circle of his friends there were successive grades of intimacy and a consequent scale of more advanced instruction. Jesus, like the Jewish teachers, drew about him a group of disciples. To those "who were without" his instruction was given in parable, both for the protection of himself and his cause and for the advantage of the disciples themselves. To these latter were given explanations of his parables in order that they might know the "mystery of the Kingdom of God." How far this esoteric teaching of Jesus, which is the heart of the gospel, was shared by others than his immediate disciples is of course difficult to say. Yet just as the influence of Judaism extended far beyond the synagogue, and many

Greeks who had not accepted it as a cult were affected by its religious teachings, it is not improbable that his influence was much more widespread than even his popularity among the masses might argue. Origen (*Ag. Celsus* 1: 22, 31; 12: 21; cf. 1: 7, 12, 24, 25, 29) speaks of the two sorts of teaching given by Jesus but leaves us in doubt as to whether he is speaking as an historian or as a commentator.

The Teaching of Jesus was Pragmatic.—Starting with the experiences of those to whom he spoke, whether those of the farmer, the fisherman, the shepherd, or the housewife, he helped them recognize the essential unity of life in the natural and spiritual realms. Jesus thus grounded authority ultimately in the reality of experience. By virtue of his own experience he assumed a highly authoritative attitude and seldom argued as to the truth of his teachings. They were rather to be subjected to the test of practical value. The evidence of their truth lay in the peace and joy which their acceptance brought, just as evidence of genuine discipleship lay in a willingness "to do the things he commanded." In this connection also should be noted Jesus' habit of adducing principles from concrete events—an element of method to be expected in one whose teaching was so vivid and vital as his. He does not, however, generalize so much as interpret the episodes he thus uses.

Jesus' Polemical Teaching.—Such teaching is by no means infrequent in the gospel records and may be fairly said to constitute an essential phase of method. The attitude of Jesus was one of criticism of the highly technical and legalistic religion which had grown up about the Law and the Temple. It is not difficult, however, to find in his polemic the constant endeavor to recall those whom he addressed to the finality of the spiritual values of their faith. That in the case of the ecclesiastics he failed is not surprising, but his failure was a means by which thousands of men and women have been brought into the larger freedom of the spirit which legalism of any sort tends to crush. If, indeed, Jesus were a critic of existing institutions and beliefs, he was also able to substitute for that which he destroyed a new group of truths which should lead their possessors into an enriched spiritual life.

The Method of the Apostles.—The problems which confronted the apostles were in many ways different from those which confronted Jesus. Jesus never organized his followers into a precisely defined group. After his death, however, his disciples immediately undertook the work of propaganda, and like their master were forced to face abuse and suffering. Yet they were able to carry the power of the gospel into the most ordinary affairs of their individual life. In so doing they organized those who accepted their

preaching into little groups of men and women,—the primitive churches. With the rise of such institutions, many of them on heathen soil, there was need of a more definite instruction, first as regards the gospel, second as regards Jesus, and third as regards the Christian life. The teacher thus was differentiated from the evangelist.

Instruction given converts to the new faith was in two fields: (1) The facts of Jesus' life and teaching. The Christians who had never seen Jesus especially needed such instruction. The evangelist or apostle who brought to them the message of salvation through him doubtless gave a certain amount of information concerning his life in Galilee and particularly concerning his death and resurrection. This seems to have been the message Paul himself uttered when he first came to Corinth. The gospel which he delivered was the one which he had himself received and it dealt with the historic facts of Jesus' life as well as the implication of these facts (1 Cor. 15: 1-7). At this point it is true one enters a much debated field, but it would seem possible, if not probable, that the "minister" Mark whom Paul and Barnabas took with them on their first missionary journey had for his duty the instruction of these early converts in the facts of Jesus' life. The fact that his name was attached to a gospel containing just the sort of information which the new convert needed argues strongly that it is a fair sample of the sort of material used for the purposes of instruction by those who, unlike the apostles and the evangelists, devoted themselves to the painstaking and minute instruction of the new converts in the facts which justified their faith (cf. Lk. 1: 1-4).

(2) The bearing of the Christian hope of a new age and the Kingdom of God upon conduct. The early Christians believed that they were waiting for the appearance of a great spiritual kingdom which would emerge out of the sky and would receive them into itself. They were, therefore, not interested in the reforming of society. They had, however, to live in the midst of heathen surroundings, and this was a task of no small magnitude. Paulinism from certain angles might be described as the application of the Gospel to human affairs. Paul's letters face the perennial difficulty of bringing home to men and women hardly free from the control of heathenism the Christian ideals of family and other forms of social life. His instruction is not formal, but consists largely of treatment of specific problems such as marriage, business slavery, the personal appearance and habits of men and women, etc., from the new point of view. In the course of time there developed what was known as the Apostles' Teaching and this became more or less systematized in the *Didache*, but it would certainly be a very serious error to think of the work of the apostles

as in any sense that of University Extension lecturers on the science of ethics. They were rather ecclesiastical statesmen engaged in organizing communities and instructing them as to the practical duties of everyday life now revolutionized by the supremacy of eschatological and "spiritual" values.

The apostolic teaching was both deductive and affected by the habits of thought of the time. Paul, in particular, proceeded with considerable logical severity from the general position which faith in Jesus as Christ involved. The Messianic program which Jesus was expected to fulfil upon his return from Heaven, carried with it certain implications relative to social life. This belief in the speedy return of their Messiah became less a source of moral renovation than of conservatism. The institutions and interests of the present historical order were soon to come to an end, and in consequence were to be endured rather than transformed. Consequently the teaching of Pauline and later New Testament literature is essentially unsocial so far as the nonreligious relations in life are concerned.

To justify, *e.g.* the subjection of women, the maintenance of slavery, and the submission to government, the apostle makes use of the methods of exposition of his day as they existed among the rabbinical teachers. Certain parallels, it is true, may be found between his thought and that of Stoicism, but they are hardly more than the expression of general principles which all ethical thought has recognized. It is impossible to find in his letters any controlling influence of such university training as he may have obtained in Tarsus. On the contrary, Paul manifests a decided hostility towards philosophy, insisting that the "wisdom of this world" is foolishness in the eyes of God and that he has a spiritual wisdom, "not of this world," which he can share with the perfect. Just what this wisdom really was his letters do not enable us to say, but it may be surmised that it was allegorical interpretation similar to that which he occasionally used.

Under the influence of his rabbinical training Paul does not hesitate to argue in a way all but unintelligible to persons trained in Greek methods of thought. Such methods are to be seen in controversies with Jewish opponents as in Gal. 3: 15-22; 4: 21-31. In similar accord with his teachers is his constant use of the Old Testament. As the authoritative oracles of God, the Old Testament literature was to Paul, and indeed to all the early church writers, a court of appeal as truly as to the rabbis. Quotations from the Scriptures are often arbitrary, the sentences being detached from the context; but the early Christians who thus were under the influence of contemporary theological methods seem never to have doubted the value of the method and in some cases approved what we must believe

were the even more pronouncedly Alexandrian methods of Apollos, who is said to have been "mighty in the Scriptures."

Occasional lack of proportion both in the treatment and method of Paul is accounted for by the fact that most of the teaching was the outgrowth of definite problems and sometimes definite questions. Occasionally he recurs to the teaching which he himself had received, but this itself was probably not very systematic. As an Apostle he claimed original authority in that he had not been instructed by the original Twelve and in that his gospel came to him directly by the revelation of the Christ. The letter to the Romans is the most systematized and academic of his writings which have survived, but it is an oratorical treatise rather than a pedagogical exposition. In it the characteristics already mentioned appear, though less pronouncedly than in Galatians. Most of his extant writings, however, are composed of independent treatments of specific problems, such as marriage, the resurrection, the position of women, justification by faith, current philosophies, and gifts of the Spirit. In them it is possible to discover that germinal system of thought which the theologians have made the vertebral column of the Christian system, but there is little of strictly pedagogical method. The nearest approach to the recognition of pedagogical principles is apparently to be seen in his refusal to give his advanced views to those who, like the Corinthians, were prepared only for the "milk" of his teaching.

This recognition of the need of progress in Christian thought becomes more apparent in the later New Testament books, such as the *Epistle to the Ephesians* and the *Letter to the Hebrews*. In the latter book the unknown author distinctly states that he intends to proceed from the "elements" of the Christian system to "perfection," *i.e.* to a sort of Christian gnosis. But the other New Testament books are religious tracts rather than educational treatises, and show no marked variation from the method of the preacher as distinguished from that of the teacher. In them all there is an exclusion of philosophical and revolutionary doctrines, an inculcation of patience pending the "day of the Lord," encouragement to maintain the hope of the approaching glorious deliverance, and exhortation to be among those who were to share in the triumphs of the returning Christ.

The Beginning of the Organization of Education.—In the New Testament, however, there are hints of more systematic instructional methods than the practical doctrinal exposition of the apostle would seem to indicate. Christianity is as much a creature of an institution as of a group of doctrines. In fact, it may fairly be said that its practices have generally preceded its doctrinal formulations.

(a) *Teaching and Prophesying.*—While we find in Paul no organized system of Christian

instruction we do find references to the "gifts" of teaching and prophesying. At this distance it is impossible to discover with absolute precision just what these "gifts" were, but the term at least indicates a differentiation of function due to abilities which were attributed to the inworking of the spirit of God. The teachers undoubtedly were those who had the ability to set forth the supportable implications of Christian hope in some more or less systematic fashion. The prophets seem to have had the capacity to set forth something similar, but doubtless with less reliance upon logic and more trust in the inspiration of the moment. Paul distinguishes both functions sharply from that of the "gift" of "tongues," which he regards as not intended for "edification." In the words of the new prophets there lay the possibilities of convincing the minds of the non-believers. In the work of the teachers, there lay means of supplementing the practical instruction which Paul himself gave in his letters.

(b) *A professional Teaching Body.* — The development of the church further tended to differentiate a group of people whose business it was to teach in spiritual matters. These Paul announced were worthy of being paid. Such persons were evidently not priests but doubtless resembled the synagogic preacher and the modern pastor. How far their instruction went and how early they became a distinct class it is now impossible to say, but that there was some instruction in Christian facts and doctrine of a formal sort seems to be evident from Galatians 6:6, and particularly from Luke 1:4, in which Theophilus is said by Luke to have been instructed (catechized). Reference has already been made to the possibility that Mark may have belonged to a class of church workers called the "ministers of the word," but there remains a great obscurity as to the exact meaning of the title. By the beginning of the second century it is clear that instruction was already pretty general in the churches. To the need of such instruction is doubtless to be attributed the reduction to writing of the traditions carried *memoriter*. Variations in the synoptic gospels may fairly well be accounted for by the assumption that they represent the types of such instruction given in different parts of the Roman Empire. With the reduction of the oral traditions of Jesus to writing (a process which was doubtless in the main complete before the destruction of Jerusalem in 70 A.D.), the possibility of genuinely catechetical instruction was established and such instruction may be assumed to have begun. We have, however, no conclusive evidence of any particular instruction of the young in Christian doctrine.

Summary. — The pedagogical methods of the New Testament, in so far as they are anything other than those of practical counsels,

may be said to have been empirically well adapted to conditions. Their subject matter was not general biblical or scientific information, but rather practical directions for living; as such they utilized the experiences of both teacher and those taught and set forth the principles of the New Christian idealism in accordance with current methods of thinking but without formal institutions or methods for instruction. The extraordinary success of the new faith must be accounted for not so much by any novelty in its pedagogical methods as by the applicability of its tenets to the Græco-Roman world. S. M.

NEW YORK, CITY OF — The present city of Greater New York, as formed by consolidation in 1897, includes the borough of Manhattan, or New York proper; the borough of the Bronx, to the north and east of Manhattan; the borough of Brooklyn, formerly the independent city of Brooklyn, and itself a consolidation of a number of towns; the borough of Queen's, being a part of Queen's County, on Long Island, and including Flushing, Hempstead, Jamaica, Long Island City, and Newtown; and the borough of Richmond, coterminous with Staten Island, in the lower bay. The combined city has an area of 320 square miles. The population of Greater New York City in 1910 was 4,766,883, or practically the same as for the state of Ohio.

Educational History. — The history of education in the state of New York during the colonial period, both under the Dutch and English rule, has been traced under the history of education in the state of New York. (See NEW YORK, STATE OF.) The first free school in the city after the Revolutionary Period, was opened in 1787 by the Society for Promoting the Manumission of Slaves, with twelve colored pupils in attendance. In 1794 the school was incorporated as the African Free School and a few years later a school-house was built in Cliff Street. By 1797 small grants were made to the school by the city corporation. The first free school for white children, enforcing no religious restrictions, was opened in 1801 by the Association of Women Friends for the Relief of the Poor, organized in 1798 by a group of women connected with the Society of Friends.

The Public School Society. — In 1805 a similar society was organized by a number

of philanthropic citizens and chartered by the legislature as the Free School Society of New York, and its powers were extended to include in its educational work "all children who are the proper objects of a gratuitous education." For the next few years the Society received aid and grants from the city and from the state legislature and in 1815 participated in the new State Common School Fund. (See NEW YORK, STATE OF.) By 1826 eight schools, with separate departments for girls in nearly all of them, enrolling 345 pupils, were in operation and gave instruction in reading, writing, figures, and religion (the children attending some place of worship regularly as a condition of admission). The Lancasterian system was employed from 1817 on. In 1818 Lancaster (*q.v.*) lectured under the auspices of the Society, which in 1820 published *A Manual of the Lancasterian System*. But in spite of the progress of the Society, many children were still unprovided for. In 1829 an inquiry, made by the Common Council, showed the following as the status of education in the city:—

SCHOOLS	TEACHERS	PUPILS STUDYING			TOTAL PUPILS
		First Elements	Geog. Gram. Arith	Higher Branches	
430 Private and Church schools	432	6907	7214	1869	15320
3 Incorporated schools	6	220	841	270	1081
19 Charity schools	25	2430	960	15	2545
11 Public schools	21	6007	475	—	6007

As early as 1822 the Society had considered the advisability of organizing instruction in the higher branches for the more promising pupils, but no action was taken toward extending the Society's work until after the reorganization in 1826. The years 1822 to 1824 were marked by the first of the Society's struggles with the religious organizations which for so long had controlled the educational situation in the city. The Society's work was largely cut into by some church-supported Lancasterian schools. The matter was carried to the legislature, and, after a long struggle, the basis of apportionment was changed by giving all of the New York City school money to the Common Council for distribution as they saw fit. The Council, after deliberation, unanimously decided to cut off all church schools from the grants, and the year 1824 thus marks an important step in the establishment of a non-denominational public school system for the city.

In 1826 the Society changed its name by charter from the Free School Society, to The Public School Society of New York, and was authorized to charge tuition fees for instruc-

tion, and to grant remittances of fees to those too poor to pay. Large numbers of parents who had previously sent their children to the Society's schools found themselves now "too poor to pay and too proud to confess their poverty." The result was that the schools, which at the beginning of the experiment had enrolled 3457 children, in six months fell off to 2999, two thirds of them being pay pupils. In 1818 the legislature had granted the Society aid from the license money paid by dealers in lottery tickets, and in 1829 a property tax of one eighth of a mill was granted in addition for maintenance. With increasing revenue, it was soon decided to make the schools free to all.

In 1827 the Public School Society organized a "junior department" in School No. 8, with a woman as teacher, for children of three years and upward, and taught on the Lancasterian system. In 1828 the Infant School Society, which had opened its first school in 1827, was permitted to establish its second school in Public School No. 10. In 1829 a report was made to the Board favoring the infant school system of training, and in 1830 the junior department of No. 8 was converted into an infant school. The new designation of primary department was now applied to such schools, and women teachers were decided upon for them. From this time on, the primary departments became an important part of the Society's work. The Society in 1830 had eleven buildings, containing twenty-one schools, and having an attendance of 6178. Two of the schools were infant schools, and three were coeducational. In 1832 the monitorial system was in large part abandoned. A committee on primary schools was appointed by the Society, and it was decided to organize ten such schools, under women teachers, for children four to ten years of age, and after the Boston plan, where the committee had visited and inspected the schools. In 1833 the first free evening schools were established, but they were abandoned a few years later. In 1834 the Manumission Society turned over its buildings and equipment to the Public School Society, and these schools became the African (in 1838 changed to colored) schools of the city. In 1834 also a special Saturday school, for the instruction of the female monitors employed in the primary schools and departments, was established, and in 1835 similar schools for the monitors in the boys' schools were provided. In 1828 the Society had appointed a "visitor" to look after attendance, and, in 1833, the title was changed to "agent" and he was also made a business supervisor for the city. In 1837 the office of superintendent of repairs was created, an office which gradually developed into that of school architect.

Creation of the Board of Education.—In 1842 the first board of education was created as a result of the claim of denominations which

desired to share in the school funds of the Society, city, and state. Each of the seventeen wards of the city was created a separate school town, and a board of education, composed of two commissioners for each ward, was to be elected by the people. Each ward was also to elect two inspectors and five trustees to act as a local school board. Existing schools were not disturbed, but public funds could not now be granted to any school or society "in which any religious sectarian doctrine or tenet shall be taught, inculcated, or practiced."

The new Board of Education began operations in 1842, opened its first school in 1843, and by 1848 had twenty ward schools, two primary schools, and two colored schools in operation. The new system was cumbersome, imperfect, and lacked the intelligent direction of the old Public School Society, but made very substantial progress. For some years the two school systems existed side by side, with more or less friction. Under the new system the old monitorial plan of instruction was either greatly restricted or entirely abandoned. The buildings erected by the Board had more and smaller classrooms and more teachers, and this and other popular features of the ward schools, as they were called, gave them a great advantage over those of the Public School Society. In 1848 the right of the Society to build any additional schools was questioned by the Board, and later prohibited by the legislature. This placed the old Society at the mercy of the new Board of Education, and in 1853 the two were consolidated. The Public School Society passed out of existence after forty-eight years of service, turning over to the city school property valued at \$604,820 46. During the period of its existence the Society had educated over 600,000 children and more than 1200 teachers. By the terms of the consolidation act, fifteen members of the Society were elected to seats in the Board of Education. The new Board assumed control of a school system consisting of 214 rooms or departments, twenty-one of which were for colored children.

Work of the Board of Education.—The Board of Education from the first began an active campaign to establish schools. During the first ten years of its existence the city increased 60 per cent in population, while the schools increased 120 per cent. In 1847 evening elementary schools were reestablished, and in 1849 a free academy which in 1866 became the College of the City of New York (*q.v.*). In 1841 a county superintendent of schools, elected by the county board of supervisors, had been created, and in 1851 the legislature granted the Board permission to appoint a city superintendent of schools, one or more assistant superintendents, and a superintendent of school buildings. By 1860 the Board had under its control forty-seven gram-

mar schools for boys, forty-seven grammar schools for girls, eighty-seven primary schools and departments, and eleven colored schools, a total of 192 schools, employing 1548 teachers, and having an average attendance of 55,050 pupils. By 1870 there were 190 schools, 2407 teachers, and an average attendance of 85,307 pupils. The population of the city at this time was 942,292, and the school population about 200,000. In 1866 the evening school system was remodeled, and the first evening high school was established. In 1869 a Female Normal and High School was authorized and established, which, in 1888, was transformed into the City Normal College. In 1869 corporal punishment was prohibited; in 1871 the first law permitting the issue of school bonds was enacted; in 1873 the Nautical School was established; in 1874 the first compulsory education law was passed, and a supervisor of truancy was appointed the following year; in 1884 the separate colored schools were abolished; in 1888 the free public lecture system was established; and in 1887, 1888, and 1890 additional evening high schools were created. The period from 1860 to 1890 has been termed the period of peaceful expansion. Only minor improvements were made during this period, the chief legislation during these three decades relating to the composition of the governing bodies, with the district trustee system as the chief point of issue. In 1871 a Department of Public Instruction, as a branch of the city government, was provided for, with a Board of Education of twelve, all appointed by the mayor. These two laws appear to have been in advance of the public sentiment of the time, and in 1873 they were repealed, and the law of 1864 virtually reenacted. This reestablished the district boards, and, in part, the district system of school control. The Board of Education of twenty-one members was to be appointed by the mayor, and the Board was in turn to appoint the ward boards of five district trustees each. The Board of Education became a legislative and supervisory body, and the district trustees appointed teachers, looked after the school property, and recommended principals and vice-principals to the central Board for appointment. In this condition the organization of the New York City schools remained until 1896.

The ward system at its best was unsatisfactory as a system, and gave rise to much complaint. In the selection of the boards it was generally believed that religious and racial questions, rather than educational efficiency, were dominant. The schools were criticized as narrow and partial, and were often suspected of proselyting the children who attended them. The criticism rose to such an extent that the legislature directed the mayor to appoint a commission to revise the school organization for the city

and to report to the next legislature. The bill proposed failed of enactment at the sessions of 1894, 1895, and 1896, the district trustee system being the center around which the battle was waged. Finally, a substitute bill was adopted which abolished the trustees and created a board of superintendents, the latter to have the power to nominate all principals, vice-principals, and teachers; to recommend the course of study; to manage and supervise the schools; and to examine and license teachers. No change was made in the Board of Education itself or in the manner of its appointment, except to make it more in the nature of a board of trustees, with power to legislate and approve, but with little power to initiate. This law was the most important reform accomplished in the New York City school department in half a century, and, with the district trustees abolished, the way for future progress was at last clear. Nearly all of the important progress in the city school system has been made since this elimination of the district system in 1896.

Brooklyn. — In Brooklyn, as in New Amsterdam, the minister preceded the schoolmaster. Probably the first school on Long Island was provided at Flatbush, in about 1653, though the first regular and full appointment as schoolmaster appears to have been in 1660. The first school tax was levied in 1661 for a school opened in Breucklyn. A third school was opened in 1663 in Bushwick (later reorganized as the first school in Williamsburg), and a fourth school was opened the same year in Bedford. Other schools were first organized in Flatbush in 1675, Gravesend in 1728, and New Lots in 1740. Two other schools were organized at Wallabout Creek and at Gowanus before the Revolution. All of these schools later became a part of the public school system of the city of Brooklyn. The Dutch language was employed at first, but from 1758 up to 1800 both the Dutch and the English language were used. In the Bushwick school Dutch was taught up to about 1835. As late as 1770 the town of Brooklyn contained only one school, with nineteen pupils. In that year a school-house was built by subscription, and the subscribers elected trustees to manage the school and to admit free those unable to pay tuition. It is claimed that the Gowanus school (later Brooklyn No. 2) was organized as a school district under the new State School Law of 1810. In 1815 the first distribution from the State Common School Fund was received, and in 1816 Brooklyn levied a village tax of \$2000 to open another school. At that time there were 552 children in the village not attending private or church schools. Six other schools are reported as having been organized in the village before the incorporation of the city of Brooklyn in 1834.

On the organization of the city, the Common Council was given power to organize the

schools. This was then done on the district system plan, the Council appointing three trustees for each school in the city, who were in turn to select the teachers and to manage the school. For the city as a whole the Council also appointed three inspectors and three commissioners, by way of integrating and harmonizing the district control. This form of organization continued up to 1843, when the first governing body for the schools of the whole city was created. The Council was created a Board of School Commissioners, with power to appoint two or more persons from each school district, for three-year terms, to constitute, with the mayor and the county superintendent of schools, a city Board of Education. In 1847 the Board of Education was authorized to appoint a Superintendent of schools for the city. In 1854 the city of Williamsburg and the town of Flatbush were consolidated with the city of Brooklyn, and the membership of the Board of Education was increased to forty-five, at which it remained during the rest of its history. In 1862 the mayor was given the power of nomination of members, and in 1882 he was given full power of appointment. In 1873 the schools were organized under the Department of Public Instruction of the city government, and the title of the superintendent was changed accordingly.

Beginning with the organization of the Board of Education in 1843, the important steps in the evolution of the Brooklyn school system may be briefly traced. After several attempts to conduct Saturday normal classes, a teachers' training school was established in 1885, with a one year's course of instruction. The first uniform course of study was prepared in 1866, and remained almost unchanged for twenty-one years. In 1874 the first unification of the grammar school work was made by a provision for uniform examinations for the completion of the grammar schools. In 1876, following the enactment of the first compulsory education law in 1874, a superintendent of truancy and five agents were appointed; in 1878 two attendance schools were provided; and in 1895 a truant school was created by the Board. In 1851 the first evening high school had been established, and in 1880 a second evening high school was provided for. In 1883 a head drawing teacher was appointed; in 1890 a supervisor of drawing and in 1896 a director of sewing and four sewing teachers. In 1897 the first public kindergartens were opened. In 1878 the Central Grammar School, with a two years' course, was opened; in 1887 the course was extended to three years; and in 1890 a four years' classical course was first outlined. In 1891 a Boys' High School and a Girls' High School were evolved out of the Central Grammar School. In 1894 the Manual Training High School was created, and in 1895 the

Erasmus Hall Academy in Flatbush was accepted and transformed into the Erasmus Hall High School. In 1883 the Brooklyn Bridge was opened, and led to the rapid growth of Brooklyn.

From the organization of the city in 1834 the Council had been permitted to appoint boards of school trustees of three to look after and manage each school. In 1851 this was definitely transformed into the "Local Committee System," of three trustees for each school. When high schools and training schools were established, local committees for these were also established, and in time the system grew so formidable that substantial progress under it was very slow, if not almost impossible. The local committee system and the unwieldiness of the large Board of Education were subjects of discussion and criticism for years, and in 1894-1895 efforts were made to secure a more centralized administration and a Board of Education of fifteen members. Before anything was accomplished, however, Brooklyn in 1897 became a part of the city of Greater New York.

Present System. — The Greater New York charter of 1897 provided for the consolidation of the old city of New York, including the Bronx, the city of Brooklyn, a part of the then Queen's County, and all of Richmond County into one greater city organization. The New York and Brooklyn Boards were continued without change, the different town and county school organizations in Richmond County were consolidated under one Board of Education, and the same was done for that part of Queen's County which was annexed. The city superintendents of New York and Brooklyn became borough superintendents, and borough superintendents were to be appointed for Richmond and Queen's. A Central Board of Education of nineteen members was to be constituted, by representation from each of the boroughs. The result was a federation, with no more disturbance of existing conditions than was necessary, and with no great powers lodged with the Central Board. In Brooklyn the local committee system was expressly continued, and this was not abolished until the new Charter of 1901. The Central Board was made the custodian, also, of all school moneys, and was required to appoint a School Treasurer and to establish a disbursing office.

The disadvantages of having four borough school boards and a loosely organized central body were so many that, after four years of trial, the plan was abandoned. In 1901 a revised charter was obtained for the greater city which unified the different parts of the school system for the first time, and with certain minor changes still continues.

The school system as at present organized is directed by a Board of Education of forty-six members, appointed by the mayor. Of

these, twenty-two are appointed from the Borough of Manhattan, fourteen from the Borough of Brooklyn, four from the Borough of the Bronx, four from the Borough of Queen's, and two from the Borough of Richmond. An executive committee of fifteen directs much of the work of the Board, and fourteen committees look after various special lines of work. The city is divided by the Board of Education into forty-six school districts, for each of which a board of five citizens is appointed by the borough president. One member of the Board of Education, designated by its president, and the district superintendent of schools having supervision of the district, are also members of each local board. These local district boards are largely advisory in function, but have some important supervisory powers over the school property of the district.

The Board of Education appoints a superintendent of schools for the city, and eight associate superintendents, who together constitute the board of superintendents, and, on their recommendation, the Board appoints the district superintendents, of whom there are twenty-six. The initiative in practically all educational matters is given to this board of superintendents, and its educational powers are large. A board of four examiners has control of the examination and certification of all teachers and principals. The Board of Education appoints a superintendent of lectures, who has charge of the free lecture system (*q.v.*) of the city; a superintendent of libraries, who looks after the libraries and library work in connection with the schools; and a board of retirement, to administer the Teachers' Retirement Law.

The Board of Education is allowed the proceeds of a three-mill tax for salaries, but all other expenses are wholly within the discretion of the Board of Estimate and Apportionment for the City, to whom the Board must apply for funds. The Board of Education possesses by law such general powers as are necessary to establish and control a complex city school system. The city superintendent of schools has a seat in the Board, with the right to speak but not to vote. He is charged with the enforcement of the compulsory education laws, and nominates all attendance officers for appointment. He assigns their duties to his subordinates, and oversees their work. He presides over the board of superintendents and the board of examiners. The board of superintendents nominates all district superintendents, principals, heads of departments, and teachers; selects all textbooks, apparatus, and supplies; nominates the directors of the special branches of instruction, and assigns the assistants to their work; recommends changes in grades, classes, and courses of study; and determines all promotions and transfers of teachers and supervisors, subject to the approval of the Board of Education. The

district superintendents are assigned to the supervision of different districts of the city, or to different branches or divisions of the educational work.

Scope of the School System.—In size and complexity the school system of the greater city is virtually a great state school system in a condensed form. The city of New York enrolls a larger number of children, employs four fifths as many teachers, and expends half as much again for education as the state of Ohio. The school census of the city exceeds a million and a half of children; about 800,000 children are in average daily attendance at the public schools; a city college, a large normal school, and branch training schools, twenty-two day high schools and a dozen evening high schools, about two hundred day and about fifty evening elementary schools, trade schools, a system of vacation schools and playgrounds, a nautical school, and an extensive evening lecture system are maintained; about 18,000 teachers, and a thousand supervisory officers are employed; and the current expenses total about thirty-five millions of dollars, and are increasing constantly and rapidly. The College of the City of New York (*q.v.*), located in Manhattan, is one of the large and important colleges of the United States. The city normal school is also a large and an important institution. Training schools are also maintained in Brooklyn and Queen's. The high schools employ about 1500 teachers, and enroll about 40,000 students. They represent different lines of instruction, there being manual training, commercial, and vocational high schools, as well as high schools of the more traditional types. A number of evening high schools of different types are maintained in the different boroughs, the evening vocational or trade schools being of an excellent type.

Educational Conditions.—The greater city has recently made very remarkable endeavors to meet the educational needs of a very complex and difficult educational situation. Most of the important progress has been made since the elimination of the district system, and the inauguration of the present system of school control. Owing to the very rapid growth of the city from births and immigration, the struggle to provide seating accommodations for all has been a long and as yet an unsuccessful one, despite the erection of numbers of excellent new buildings. The buildings erected within the past fifteen years are among the best of their kind. The educational problem is rendered especially difficult by the fact that New York City is one of the most cosmopolitan cities in the world, and hence has large numbers of children of foreign parentage in the schools. Over one third of the total population is foreign born, and about three fourths of the population is of foreign parentage. The Germans, Irish, Italians, Russians,

Austrians, and English, in the order given, are the leading foreign nationalities, though almost every foreign nationality and race is represented in the city's population. This, with the congestion of population, the large amount of poverty, and the absence of the wholesome home restraints to which the children of these foreign peoples are accustomed in Europe, makes the educational problem in the city especially difficult. The peculiar conditions call for a centralized educational administration and for a high quality of educational leadership. To cope better with the truancy and child labor situations new legislation of an important kind has recently been obtained, and the metropolitan school census law recently enacted, under which the police make an annual house to house investigation, gives the city of New York the best school census law to be found in the United States. As might naturally be expected in a city where the schools were for so long relatively poor and the public school system incomplete, and in a city possessing so large a foreign element, the private school and the parochial school abound, though these schools have not increased so rapidly since the public schools have come to represent a higher type of public education. E. P. C.

NEW YORK, THE COLLEGE OF THE CITY OF.—The capstone of the free public educational system of New York City. In response to the repeated proposals to found a Latin School or an Academy, a committee was appointed by the legislature of 1846 to study the advisability of such a step. The plan for an institution of higher learning was submitted to the people in the election of 1847 and was carried by an overwhelming vote. The Free Academy opened its doors with 143 students and a faculty of nine, under the leadership of President Horace Webster. The Free Academy was an attempt to evolve an institution that combined both high school and college, and proved most successful. Its students and its faculty gradually increased,

THE COLLEGE OF THE CITY OF NEW YORK

its standards were steadily raised until it reached the level of the best of the eastern colleges.

In 1866 the name was changed to The College of the City of New York, a title more in keeping with the rank and the scope of its work. Under the direction of its second president, General Alexander S. Webb, the sphere of work of the college increased in such proportions that annexes were built and temporary quarters were hired in adjoining buildings. By the close of the century, the pressure of a rapidly growing student body made it evident that new quarters were imperative. The city provided \$5,000,000 for a new home of five buildings on Washington Heights, with an equipment unsurpassed. In 1908 these new structures were given over to a student body of over 4000, including the preparatory classes, an instructing corps of about 230 under the presidency of John Finley. The college not only provides tuition for 1300 college students and over 2500 preparatory students, but also special instruction for over 3000 teachers of the city schools and for 500 evening students, and musical recitals and lectures for the promotion of higher musical interests to tens of thousands. All these activities are carried on through an annual appropriation of about \$600,000.

The aim of the college is to enable all ambitious young men, properly prepared, to obtain the cultural advantages of a higher education, to foster in them a civic and social conscience, to develop an ideal citizen body. A free education of college grade is open to all the city's sons, irrespective of race, creed, or class. Unlike the civic universities of England, often placed in the same class, the College collects no fees, makes no charges for books and apparatus, and does not depend upon the bounty or the philanthropy of any private individual. (See MUNICIPAL COLLEGES AND UNIVERSITIES.)

The present organization of the College dates back to 1900. Prior to that year the trustees of the College were also the members of the Board of Education of the city schools. Occupied with the vexing problems in the education of 750,000 children, the Board could not properly direct the policies of this single institution. In 1900 the Legislature gave the College a separate board of nine trustees, who were to be appointed by the Mayor of the City for a definite term. Beneficial results soon followed in the wake of this change, for it brought increased familiarization with the needs of the College, and concentrated effort towards the realization of the cherished plans for a new and fitting home.

The standards of admission are on the same high level as those in the leading eastern colleges. Students are admitted by a certificate of the College Entrance Board, or by a diploma of the city high schools or of Townsend

Harris Hall, the Preparatory Department of the College.

The spirit infused by the early authorities reflected their West Point training. The College is still characterized by severe discipline, rigorous mental work, a strict marking system, an emphasis on those subjects that give mental fiber. The classics are studied very intensively, and more mathematics is usually required than by other colleges in the country. The existing curriculum is an attempt to retain the rigor of the old course and rational latitude for personal choice. Six courses are offered: these are grouped under two heads, viz. those leading to the B.A. degree,—classical, Latin-French, modern language; and those to the B.S. degree,—general science, biology-chemistry, mechanical. All work is prescribed through the sophomore year. In the junior and the senior year ample opportunity is given, through electives, for the pursuit of special interests and the cultivation of individual powers. The College was the first to establish a chair in English as well as the first to organize a Department of Mechanic Arts. It was one of the pioneers in the movement to introduce the sciences and place them on a par with the classics. It responded to the pressure of needs of the day by organizing in the last decade departments of public speaking, physical training and hygiene, education, economics and social science, and music.

In addition to the regular college course, the College cares for a Preparatory Department, Townsend Harris Hall, with more than 2500 pupils. In the hope of reaching those worthy young men who through force of circumstances were denied the benefits of a college education, the Evening Sessions were organized in 1910. A freshman class of over 200 enrolled, each meeting the same entrance requirements as those which govern admission to the day sessions. Over 500 evening students are at present pursuing regular studies of college grade, striving either to complete an interrupted course, or merely for personal development. In order to meet the needs of those teachers of the city school system who are endeavoring to improve their professional standing, it offers under its auspices regular courses in education, English, comparative literature, science, etc. Over 3000 teachers are in regular attendance. The successful completion of these courses entitles the teacher to partial exemption in promotion examinations given by the Board of Education of New York City.

The student body is different from that which one finds in the average eastern college. The enormous population of the city furnishes the students. There is no dormitory life. The young men scatter over the city each day when college labors and activities are over. The great majority of these students would

be denied a college education if it were not for the opportunity which the College extends to them. Social life and social spirit, however, are not absent. The students form their friendships in one of a large number of literary, debating, or science societies, and in the round of popular fraternities. Though the institution is nonsectarian, it is not irreligious; the Y. M. C. A., Y. M. H. A., the Newman Club, the Menorah Society, keep alive the religious spirit which many students bring to the College.

A municipal college, more than any other, must constantly be alive to its obligations to the community. The College of the city of New York, in its attempt to meet its social responsibility, has given its best graduates to the city school system. In the capacity of teachers, principals, superintendents, supervisors of evening education or of free public lecture centers, those who gained their inspiration at the College are striving in the colossal task of Americanizing the cosmopolitan and foreign population of the city. The College has its full quota of leading members of the New York Bar, of eminent surgeons, of illustrious engineers, of experts in sanitation, of leaders in architecture and in every phase of human endeavor.

NEW YORK SCHOOL JOURNAL. — SEE JOURNALISM, EDUCATIONAL.

NEW YORK, STATE OF. — First settled by the Dutch in the early part of the seventeenth century; it was surrendered to the English in 1664, and remained under their rule until the Revolution. In 1788 New York entered the Union as one of the thirteen original states. In size, the state is the largest east of Illinois and north of North Carolina. Its area is 47,654 square miles, which is about the same as that of England. The total population in 1910 was 9,113,614, which was greater than that of any other state, and in its density of population, 191.2 per square mile, the state ranks fifth. For administrative purposes the state is divided into sixty-one counties, and these in turn into superintendency districts, cities, towns, and school districts.

Educational History. — *Under the Dutch.* — New Netherlands was founded by the Dutch West India Company as a commercial venture. New Amsterdam (now New York City) was the seat of the government and the principal settlement. By the time of the English occupation about a dozen villages had been settled, principally on western Long Island and along the Hudson River. So far as is known, the first school of the colony was opened at New Amsterdam in 1638 by Adam Roelantsen (the formerly accepted date of 1633 is now considered to be unauthorized). This school, as was the custom in the Netherlands, was a parochial school, the joint con-

cern of the civil authorities (the West India Company) and the Reformed Dutch Church. The former paid the salaries and exercised the principal control; the latter licensed the schoolmasters and exercised a certain supervision over the teaching. The schoolmaster was (generally) also the reader (*voorzitter*) and precentor (*voorsanger*) in the church, and often acted as sexton besides. In addition to his salary from the company he received tuition fees from all the pupils except the poor, who were taught free. In 1653 New Amsterdam received a city charter, and the school came more under the control of the city government. This school appears to have been maintained continuously from its foundation and is now probably the oldest elementary foundation existing in America. The outlying villages for the most part conducted parochial schools similar to that of New Amsterdam. In the case of these, however, the West India Company did not pay the salaries (though occasionally rendering assistance), nor did it exercise control. The support and control in each village lay in local court and church. In 1652 a trivial (Latin) school (*q.v.*) was opened by the Company in New Amsterdam, but lapsed in a short time. In 1659 another Latin school was opened under the joint support and control of the city and the Company. Private schoolmasters were found in New Amsterdam from an early date. These had to be authorized by the director and council. In the elementary schools the curriculum consisted of reading, writing, less of the arithmetic, the catechism, and certain prayers. Girls attended on equal terms with the boys. Besides the various Dutch settlements certain English-speaking villages were chartered. Possibly many of these had schools, but little is known of them.

Under the English. — After the English occupation the schools of the Dutch communities continued, in most cases, as public parochial schools until about the Revolution. Among the English inhabitants the principle of private enterprise in school affairs on the whole prevailed, as elsewhere in the colonies. Teachers were in theory licensed by the Governor or the Bishop of London. In New York the city authorities and the several churches did a little for the education of the poor by way of charity. In 1702 "An act for encouragement of a grammar free school" was passed, which provided for the appointment, by the Governor, of a schoolmaster to instruct the male children of French, Dutch, and English parents in reading, writing, English, Latin, and Greek. The school was to be supported by taxation, and the schoolmaster to be licensed by the Bishop of London or the Governor of the colony. The law was in force for a period of seven years, and at its expiration the school lapsed. It was not until 1732 that any further legislation took place.

Private instruction and private schools supplied such secondary, as well as elementary, schools as existed during the interim. Trinity School, in New York, dates from 1710. In October of 1732 "An Act to encourage a public school in the city of New York for teaching Latin, Greek, and Mathematics," was passed. The school was to be supported by the income from licenses issued to hawkers and peddlers, and was to be under the visitation of the justices of the supreme court, the rector of Trinity Church, and the aldermen of the city, who could remove the schoolmaster, for cause, and appoint his successor. Twenty free scholarships, distributed among the various counties, were provided. This law was also for a term of seven years, and after eight years this school, too, was discontinued, and the colony once more fell back entirely on private tuition and patronage.

The Society for the Propagation of the Gospel (*q.v.*) early organized elementary schools which in this colony formed no inconsiderable part of the elementary education of the English-speaking villages. Its first school in the colony was organized at Rye, in 1704, and between then and 1775 about sixty teachers were employed, schools being maintained at Albany, and in and about New York.

In 1746 the legislature passed "An Act for raising the sum of £2250 by a public lottery, for this colony, for the advancement of learning and toward the founding a college within the same." This was the first act looking to the foundation of a college for the colony, and the final outcome, after much discussion, was a royal charter from King George II, in 1754, creating King's College, afterwards Columbia University (*q.v.*). Instruction was organized at once, and continued up to the Revolution and the occupation of New York by the British. A grammar school was maintained in connection with the college.

Early State Legislation — The first state constitution was adopted in 1777, and amended in 1801, but neither the original nor the amendments contained any mention of education. There was little of an educational nature left in the state at the close of the Revolution. A few private and parish schools, a few academies, and a defunct college were about all. Excepting the college, the colony had never considered education as a public function.

In January, 1784, two months after the British left New York, Governor George Clinton, in his message to the legislature, gave the first official expression of the need of educational institutions for the state, and recommended "the revival and encouragement of seminaries of learning." The recommendation received prompt attention, but the final result was a bill to establish a state university. The friends of the defunct King's College now presented a petition for its reorganization, which was substituted for the

proposed bill, and the result was the creation, on May 1, 1784, of the Board of Regents of the University of the State of New York, with King's College, now revived and renamed Columbia, as the central feature of the plan. The Regents, of whom there were 31, though the number was further increased to 64 later in the same year, were empowered to found schools (seminaries or academies) and colleges in any part of the state, and to endow them, and every such school or college was to be deemed a part of the University. During the next three years the reestablishment of King's College (Columbia) occupied the entire attention of the Regents, and practically nothing was done toward establishing academies (or colleges) elsewhere in the state. The dissatisfaction arising from this condition of affairs led to the passage of a new bill, in 1787, under the title of "An Act to institute a university within this State, and for other purposes." All previous acts were repealed; Columbia College was set off, under a separate Board of Trustees, to work out its own development, though regarded as a part of the new and more comprehensive University; and a new Board of Regents of the University of the State of New York of 21 members was created, to whom was given the visitation, inspection, and oversight of "all the colleges, academies, and schools which are or may be established in this State," with power to make by-laws, confer degrees, receive and apply funds, and incorporate colleges and academies. All colleges and academies were to be under their own Boards of Trustees, and all colleges were to have the same corporate rights as Columbia. The University of the State of New York, as thus constituted, has since continued, and has exerted an important influence in the incorporation of academies and colleges within the state. On November 15, 1787, the first two academies (Erasmus Hall and Clinton Academy) were chartered. Since 1787 an annual report of the work of the colleges and academies has been regularly made to the legislature, and since 1835 the condition of the colleges and academies has been published with increasing detail. The University has devoted its energies to examining and supervising, and has not engaged in teaching. In 1863, however, the plan of an annual convocation was instituted, and in 1889 university extension was recognized as one of its proper functions. Professional and technical education, libraries, and museums have also been included.

The bill reconstituting the Regents provided only for secondary and higher education. In 1787 the Regents, in a carefully prepared report, called attention to the deficiencies in their articles of organization, and expressed the feeling "that the erection of public schools for teaching reading, writing, and arithmetic is an object of very great importance which

ought not to be left to the discretion of private men, but be promoted by public authority." Again in 1793, 1794, and 1795 the Regents called the attention of the legislature to the desirability of establishing elementary schools. It was not until 1795 that any definite action was taken by the legislature, and the schools created then were organized independently of the authority of the Regents.

Aside from the constitution and reconstruction of the Board of Regents, the first legislative act relating to education was that of May 10, 1784, directing the Commissioners of the Land Office to lay out the unappropriated lands of the state into townships, six miles square, and to reserve in each a lot of 300 acres for the support of a minister of the Gospel, and one of 690 acres for the support of a school or schools. This act must be regarded as merely one of encouragement to religion and learning, and not as a recognition of the principle of public support of schools. In 1790 the legislature made the beginnings of the Literature Fund by authorizing the Regents to take possession of and lease out certain state lands, applying the income to aiding colleges and academies. In 1791 an act was passed which authorized six men, in the town of Clermont, to receive certain excess excise fees and fines collected in the town, and "not wanted for the relief of the poor," and with such funds to build a schoolhouse and maintain an elementary school.

The First School Law.—In 1795, perhaps largely in response to an urgent recommendation of Governor Clinton in his annual message of that year, an "Act for the Encouragement of Schools" was passed. This was the first general school law enacted by the state. It was in the nature of an experiment and was to run for five years only. The sum of £20,000 was apportioned from the state treasury, annually for five years, "for the purpose of encouraging and maintaining schools in the several cities and towns in this state, in which the children shall be instructed in the English language, or be taught English grammar, arithmetic, mathematics, and such other branches of knowledge as are most useful and necessary to complete a good English education." The quotas of the counties were indicated, and within the counties the distribution was made to the towns on the basis of taxable wealth. Each town was to select from three to seven commissioners, who were to supervise the schools and apportion the money among the districts. The inhabitants of the different sections of each town were to associate themselves together for school purposes, and to elect two or more of their number as trustees to employ teachers and to confer with the town commissioners on all school matters. The town school money was to be apportioned to each district on the basis of the number of days taught in each, but no

apportionment was to be made unless the town commissioners approved of the teachers selected for the schools. Here may be seen the beginnings of the certification of teachers in the state of New York. By 1798 sixteen of the twenty-three counties organized at that time reported 1352 schools, and 59,660 children in attendance. An effort to extend the law in 1800 failed, and the law expired by limitation. It was not until 1812 that common schools were again organized.

In the meantime certain other important legislation was enacted. In 1799 four successive lotteries to raise \$100,000 were authorized; \$12,500 was to be paid to the Regents for distribution among the academies, while the remainder was to be placed in the treasury for the use of the common schools, and in such manner as the legislature might later direct. In 1801 another lottery, to raise \$100,000, one half of which was to be similarly put into the treasury for the common schools, was authorized. In 1803 the Comptroller was directed to invest the common school money in good real estate. Each year, from 1800 on, the Governor of the state urged the legislature to reestablish the common school system, and in 1805 Governor Lewis sent a special message in which he recommended the appropriation of all state lands to a school fund, and the creation of a common school system, to be under the supervision of the Regents. Twenty-one academies had been incorporated by this time, but no common schools. The Regents also made similar recommendations to the legislature for three successive years. The result of all these recommendations was the creation of a permanent state school fund by the legislature in 1805. The act as passed provided that the net proceeds of the 500,000 acres of vacant state lands first sold should be applied as the basis for a permanent fund for the support of common schools. The income was to be safely invested, and no distribution was to be made until the annual interest should amount to \$50,000 a year. In 1805 the legislature also chartered the "Public School Society of the City of New York," the purpose of which was to establish free schools in the city "for the education of such poor children as do not belong to or are not provided for by any religious society." This Society began to receive aid from the school fund in 1812, was granted a city tax in 1831, and was dissolved in 1853, after having educated over 600,000 children and accumulated property worth \$450,000. (See NEW YORK CITY.) It rendered very valuable service to the city and to the state. Further legislation in 1805, 1807, and 1808 added the lottery money and certain bank stock to the permanent school fund. By 1810 the annual income from the fund amounted to about \$26,000, and in 1811 the Governor was authorized by law to appoint

a commission of five to report a system for the organization and establishment of common schools for the state. This commission made a careful inquiry and reported in 1812. They also submitted the draft of a bill which contained the main features of the law of 1812, and of the common school system up to 1838.

By the law of 1812 the several towns of the state were to be divided into school districts by three town school commissioners, elected as town officers; each district was to elect three district trustees, who were to care for and superintend the school of the district; the interest of the school fund was to be apportioned to the counties and to the towns on the basis of their population by the last U. S. census, and from the towns to the school districts according to the number of children in each, five to fifteen years of age; each town must raise locally as much money as it received from the state; and all state and local taxes were to be used for teachers' salaries. The system of common schools thus established was placed, not under the Regents, but under a new official to be known as a Superintendent of Common Schools, to be appointed by the Council of Appointment. Thus arose the dual system of school administration which characterized New York up to 1904. In 1814 each town was further authorized to elect six additional inhabitants to act with the town commissioners, as school inspectors, and one of their duties was to examine and license teachers. In 1818 the state library was established, and in 1836 the New York State museum. In 1844 the library was placed under the control of the Regents, and in 1889 a library school was established. In the same year the state museum was made an integral part of the university. In 1821, largely in indignation at the removal of the very efficient first Superintendent, Gideon Hawley, the office of Superintendent of Common Schools was abolished, and from then until 1854 the Secretary of State acted *ex officio* as Superintendent. In 1819 the annual state appropriation for schools was raised to \$80,000, and in 1819, 1826, and 1827 the school fund was increased by various additions from stocks, land sales, fees, etc. The new constitution of 1822 further devoted the proceeds of all lands belonging to the state to the permanent fund for common schools. By 1831 a fund of \$1,696,743.66 had been built up. In 1822 the State School Department was clothed with the important power to hear and decide appeals on questions of school law. In 1826 Governor DeWitt Clinton (*q.v.*) recommended the establishment of a seminary for the training of teachers, and this recommendation was renewed by Governor Flagg, in 1830. By 1828 the income of the Literature Fund had reached \$10,000, and this was distributed to the forty-four academies then existing. By 1839 there were 106 academies reporting.

In 1830 the first convention of teachers assembled at Utica. In 1835 the school district library system was inaugurated by authorizing a district tax, therefore, of \$20 the first year, and \$10 yearly thereafter.

New Interest in Education — In 1837 New York received \$4,014,520.71 from the U. S. Treasury as the state's share of the U. S. Deposit Fund (Surplus Revenue of 1836), and this, together with the new movements in Massachusetts and other states, seems to have stimulated a new interest in education in New York. (See articles on separate states.) It was decided at once to devote the income from the Deposit Fund to schools. Of the income, \$110,000 was appropriated for common schools. This was to be distributed in the same manner as the income from the state school fund, but, to share in it, districts were now required to extend the school term from three to four months; \$55,000 was also to be distributed in the same manner, to be used for school libraries only until 1842, and thereafter for libraries or teachers' salaries; \$28,000 a year was to be used by the Regents to aid academies; and the balance of the income was to be added to the principal of the permanent school fund. Following this a number of important laws were enacted, looking toward free schools and supervision, which finally culminated in the rate bill compromise of 1850 and the reestablishment of the office of State Superintendent of Schools in 1854.

In 1839 the appointment of unsalaried county boards of visitors marked the beginning of county supervision. They were to make suggestions for improvement, and as a result of their supervision, the law of 1841 provided for a Deputy Secretary of State for Schools, and for a deputy superintendent of common schools for each county. These latter were to be appointed by the supervisors of the county, were to examine and certificate teachers for the county, and were to have general supervision of all the schools of the county, subject to the rules and regulations of the state office. The town inspectors were reduced to two, and the certificates issued by the town authorities were limited to the town. In 1843 both the town commissioners and inspectors were abolished, a town superintendent of schools succeeded to their duties and functions, and the name of deputy superintendent was changed to that of county superintendent of schools. The Secretary of State was made *ex officio* a Regent in 1842, and in 1843 was also granted power, on proper recommendation or evidence, to grant state teachers' certificates. In 1847 the office of county superintendent was abolished; in 1854 a separate state department of public instruction was created and a State Superintendent of Public Instruction appointed; and in 1856 the office of town superintendent of schools was in turn abolished and the office of school com-

missioner (one for each legislative assembly district, to be elected by the people for three-year terms) was in turn created. At this point the system of supervision created remained fixed until very recently.

The period up to 1854 was also characterized by new undertakings with reference to teachers and their training, and the impulse given then has continued down to the present. In 1834 the first teachers' training classes had been established, one in each of the eight judicial districts of the state. The academies were appointed to give the instruction, and the first classes were opened in 1835. This was probably the first public provision for the professional training of teachers in the United States. An appropriation of \$500 for books and apparatus, and \$400 annually for an instructor, was made by the state for each Senatorial district. After ten years, all state aid to the academies for training classes was withdrawn, and the state established its first normal school at Albany (1844), but after another five years, the demand for local training classes became so strong that they were reestablished, and the aid reextended in 1849 has never since been withdrawn. In 1877 high schools and academic departments were also admitted to the privilege of maintaining training classes. A second state normal school was established at Oswego in 1863; three additional schools at Cortland, Fredonia, and Potsdam in 1866; three more at Geneseo, Brockport, and Buffalo in 1867; three more at New Paltz, Oneonta, and Plattsburg between 1886 and 1892; and a twelfth state school at Jamaica in 1893. In 1881 some standards for the admission of pupils to the normal schools were imposed, and these have since been very materially added to. In 1843 the first teachers' institute was held at Ithaca, and in 1847 teachers' institutes were placed under state control and the first state aid to them (\$60 to each county organizing) was granted. In 1859 this was doubled, and in 1860 the appropriation for the state was fixed at \$8000. In 1862 local authorities were permitted to pay teachers their salaries while attending; in 1881 a state corps of institute conductors was organized; in 1885 attendance was made compulsory; and in 1892 a state bureau of institutes and training classes was organized under the State Superintendent. The state appropriation for institutes steadily increased up to 1910, when they were abandoned.

Battle for Free Schools. — The application of the U. S. Deposit Fund to education, and the various state and contemporary movements for educational improvement, seem to have stimulated an interest in providing free common schools for all, and the next decade witnessed a great struggle for free schools. In the convention which formed the new state constitution of 1846, a clause providing for free

schools, to be supported by general state taxation, failed by a narrow margin. In 1849 the Secretary of State made a strong plea for the abolition of the rate bill (*q.v.*) and for free schools for all, and that year "an Act establishing free schools throughout the state" was passed. The act, however, was not to be effective unless approved by a referendum vote of the people at the November elections. The result was a vigorous campaign for free schools, and the election was carried by a vote of 249,872 for and 91,951 against. Schools were to be made free to all children, five to twenty-one years of age; county supervisors were to levy a county tax twice that received from the state; and any needed balance was to be raised by district taxation. So vigorous were the opponents of free schools, however, that the legislature of 1850 called a second referendum on the repeal of the free school law. This the people failed to favor by a vote of 184,308 for repeal and 209,316 against. Strong objections still existed, and the legislature was flooded with petitions for the amendment or the repeal of the free school law. Finally, in 1851, a compromise bill was enacted, entitled "an Act to provide free schools throughout the state." Schools were declared free to all children, five to twenty-one years old, and an annual state tax of \$800,000 was to be levied on all property for their support. The proceeds of this tax, together with the income from the state school funds (then \$300,000 a year), was to be distributed to the different school districts of the state maintaining a six months' term, one third to all equally, and two thirds on their school census. Any additional money needed was to be obtained by the rate bill, though all indigents were to be exempt. In 1853 the free school law of 1849 was declared unconstitutional, though this decision, owing to the compromise of 1851, had little effect. The cities generally refused to employ the rate bill, and early made their schools free. In 1857 the state tax was changed to a three fourths of a mill tax, which increased the state aid one third. Still, in that year, \$427,956 was collected from rate bills. Finally, in 1867, the state tax was increased to 1½ mills, and the rate bill was abolished in the state.

Other Legislation — Some other significant school legislation was also enacted during the period of struggle to establish school supervision, the training of teachers, and free schools. In 1846 the first provision by the state for the education of Indian children was made, and in 1856 the Indian schools were placed under the charge of the State Superintendent of Public Instruction. In 1853 the first compulsory school law was passed. The law provided that vagrant children, five to fourteen years of age, could be taken before a magistrate and their parents compelled to agree, in writing, to send them to school four months each year until they were fourteen years old. Mas-

sachusetts alone was earlier in the enactment of such a law. Public sentiment was against it, however, and the law but little enforced. In 1853 the union free school law was passed. Under this, any district, or union of districts, could provide a free school, levy taxes for the same, and establish academic (secondary) departments when deemed necessary or desirable. The elementary schools were under the supervision of the state, county, and local school authorities, but any academic departments established were subject to the inspections and regulations of the Regents. These schools materially helped the movement for free schools, though their dual form of supervision later led to conflicts between the two state systems and emphasized the need for a unification. An attempt at this unification was made in 1836 and 1837, but the movement failed. In 1870 a bill providing for uniformity was passed, but was vetoed by the Governor. Here the matter rested until 1898. In 1865 the Regents' preliminary examinations were held for the first time, and in 1878 the first advanced examinations. In 1866 the power to condemn land for school purposes was given to the local school authorities, and in 1868 a state institution for the blind was established at Batavia.

The period from 1868 to 1886 has been termed the period of quiescence in the history of the New York school system. There was but little legislation, and none of any fundamental importance. No extension of the powers of the State Superintendent took place, during this period, and the increase in both state and local taxation barely kept pace with the increase in population. In 1874 a second compulsory education law was passed, this time requiring attendance of all children, eight to fourteen years of age, for fourteen weeks each year, eight of which must be consecutive. The local authorities were empowered to enforce the law, but little was accomplished under it. In 1875 it was provided that the State Superintendent should issue life diplomas only on examination, instead of upon recommendation. In 1876 the counting of private or parochial school pupils for public school purposes was prohibited. In 1883 the rule of the Court of Appeals, requiring intending law students to pass an examination, was enforced by the Regents, and in 1889 intending medical students were also required to pass the Regents' examination.

From 1886 to 1904.—Beginning about 1886, and continuing down to the present, the renewal of interest in educational legislation and the extension of the central control have been marked. In 1885 religious instruction and exercises had been prohibited in the schools, and in 1887 the wearing of any distinctive garb was also prohibited. In 1887 a uniform system for the examination of teachers was adopted by the State Superintendent. This was at first acquiesced in by the school

commissioners of the state, but was made mandatory by law in 1894. The same year institutes were changed from county institutes to school-commissioner-district institutes. In 1889 the supervision of all teachers' training classes in the high schools and academies of the state was transferred from the Regents to the Superintendent of Public Instruction. In 1889 the laws relating to the powers and duties of the Regents enacted during the previous century were revised and consolidated. In 1890 better regulations for the government of the normal schools were provided. In 1891 the university extension department was established by the Regents. In 1892 the old district library law was revised, and districts were required to duplicate the state grants Specifications and plans for schoolhouses, varying in cost from \$600 to \$10,000 were also secured and furnished by the state office from this year on.

In 1894 a new state constitution was adopted. This made the first definite constitutional provision for a state school system, made the Regents a constitutional body; safeguarded the different funds; and prohibited aid to denominational schools. In the same year the "Consolidated School Act," the first consolidation and revision of the school laws since 1864, became a law. A new revision of the compulsory education act, which changed this into an effective law, and the creation of a Board of Examiners and the placing of full control of all teachers' examinations in the hands of the State Superintendent, were also enacted in 1894. In 1895 a law was passed requiring that all teachers employed in elementary schools, after 1897, must have taught three years, or be graduates of a three years' course in a high school or academy and have had a course of thirty-eight weeks in a teachers' training class. Teachers in city schools must have had a two years' training course. The Biennial School Census Act and the Horton Act were also passed in 1895. Under the Horton Act, the Regents were given an automatically increasing appropriation to enable them to aid properly the academies and high schools of the state. The result of this law was a marked increase in both the number of such schools and the annual appropriations for them. In 1896 school districts were permitted to contract with other districts for the education of their children; city institutes and state summer institutes were established; and all teachers' certificates were to be made to expire at the end of the official school year. In 1900 new uniform regulations for the granting of teachers' certificates went into effect, and all certificates granted in the future were to be based on the use of the same questions as for a first-grade certificate. In 1903 the compulsory attendance law was again revised, and made more effective. In 1904 a Teachers' Information Bureau was established in the department.

Unification; Recent Advances. — The year 1904 saw the final unification of the two educational departments of the state school system, and the ending of more than a quarter century of friction. After 1870 no attempt at unification seems to have made any headway until about 1898. In this year a large number of bills for the unification of the two departments, or for a clearer demarcation between them, were introduced in the legislature, but no action was taken. In 1899 the Roosevelt Commission was appointed to study the situation. It reported a bill for the unification of the two departments in 1900, but the bill failed of passage. By 1903 the feeling had become so bitter that there was a deluge of bills on the subject, none of which passed. Instead, the legislature appointed a joint committee to study the question and to report to the legislature the next year. The result was the Unification Act of 1904, providing for a reduced Board of Regents, for membership for limited terms instead of for life, and for essentially the present form of state educational organization. The first Commissioner, however, was to be elected by the legislature instead of by the Regents. This law took effect April 1, 1904, and since then the Regents and Commissioner have construed the law liberally, and in the interests of the schools of the state. A state educational building, to house the departments, the state library, and the state museum, was provided for in 1906; trade schools were authorized, and the new school census law was passed in 1908; and the compulsory education law, as it related to cities and school systems having a superintendent, was further revised and strengthened in 1909. In 1909 the consolidated school law, as codified and consolidated by the State Board of Statutory Consolidation, was passed, and the further revision, recodification, and elimination of this, as made by the Education Department, was accepted by the legislature in 1910. In this the working arrangements of the Regents and Commissioner, as practiced since 1904, were incorporated into law. The most important legislation in 1910 was the substitution of district superintendents of schools (beginning January 1, 1912) for the old popularly elected school commissioners, in existence since 1856. About twice as many district superintendents as school commissioners were provided for, so as to reduce the size of the supervisory unit one half. The legislature of 1910 also amended the industrial education law, by including agricultural instruction; passed a retirement law for teachers in certain state institutions; and abolished the teachers' institutes, formerly conducted by the state. The most important legislation of 1911 was the teachers' retirement fund law. Two other important laws permit courts to legalize proceedings for school bond issues, and create a state

advisory board in relation to agricultural education and country life advancement.

Present School System. — The Board of Regents for the University of the State of New York, and their executive officer, the Commissioner of Education, have a centralized control over the educational system of the state to a degree found in scarcely any other state. Educational functions, which in other states are intrusted to county superintendents and county boards of education, are here given to the Commissioner of Education. The only local unit possessing much power is the school district, which in New York still exercises rather large powers.

The Board of Regents, as reorganized in 1904, now consists of twelve members, elected by joint ballot of the legislature and in the same manner as Senators are elected. Their term of office is twelve years, one member going out of office each year. The officers of the Board are a Chancellor and a Vice-Chancellor, elected from their own number and serving without salary, and a Commissioner of Education, who is to be "the chief executive officer of the state system of education and of the Board of Regents."

The Board of Regents form a supervisory and examining body for the entire secondary, higher, and professional school system of the state, and possess rather unusual powers. The University of the State of New York is a comprehensive term, the University including all schools under the supervision or control of the Board of Regents. The University, as such, employs no professors, however, and does no teaching. The annual convocation is a meeting held for the consideration of educational problems, and at this meeting the Regents may confer honorary degrees. The Regents possess legislative power, subject to the constitution and laws of the state, over the educational system of the state. They may incorporate and charter, according to law, any institution or association for the promotion of literature, art, science, history, or similar purpose, and no such institution can be incorporated by a general law without the consent of the Regents. The state library and the state museum, including the office and staffs of the State Geologist, State Palaeontologist, State Botanist, and State Entomologist, are departments within the university, and the Regents may establish other departments or divisions as they deem useful or expedient. It is unlawful to use the name college or university within the state, except as authorized by the Regents; no institution in the state may confer degrees unless it has \$500,000 in resources; and the selling or granting of degrees by unauthorized institutions is prohibited. All entrance to the professions of medicine, pharmacy, and optometry must be by Regents' examinations, law alone not being under their control. The Regents also

examine and approve for practice all nurses and public accountants. They establish standards and examinations for graduation from the secondary schools of the state, issuing Regents' certificates showing the subjects passed and the "counts" or units made. They may register foreign and domestic institutions of learning of all kinds, and may evaluate their diplomas in New York terms. They are authorized to extend increased educational facilities to the people in such forms as they deem wise, and to this end are authorized to buy and loan books, maps, lantern slides, pictures, etc. All academics, academic (secondary) departments of public schools or other institutions, and all libraries and museums must report to the Regents annually, and the Regents' rules and regulations must be complied with if such institutions are to share in the financial grants. Money grants made to libraries can be spent only for books approved for purchase by the Regents. All institutions under the supervision of the Regents must be open at all times to inspection of the Regents or their representatives.

The Commissioner of Education holds office at the pleasure of the Regents, and is paid \$7500 salary, and \$1500 additional in lieu of all traveling expenses. In his selection, residence within the state is not essential. As the chief administrator and executive officer for both the common schools and the secondary and higher schools of the state, he possesses large powers. The Regents may decide policies, but the Commissioner executes all policies once decided upon, and enforces all the educational laws of the state and the rules and regulations of the Regents. He has general supervision over all schools and institutions of an educational nature; may visit and inspect them as he deems best; and may advise the officers of any schools. He is also given supervision of the different normal schools and the normal college of the state; determines the number of teachers for each, and their salaries; approves all appointments to the different faculties; countersigns all diplomas; and appoints the local boards which have immediate control of the different schools. *Ex officio*, he is a trustee of Cornell University, and he directs the annual examinations for state scholarships in the university. He may remove from office any school officer in the state for neglect or willful violation, and may also withhold state school money from any school districts for the same cause. He has power to require information and evidence, administer oaths, and to bring proceedings to enforce the educational laws or the orders of the Regents. He is given and may execute such further powers and duties as the Regents may charge him with. He prepares all registers and blank forms for teachers and school officers; all school officers must report to him annually, and as requested; he approves all

plans for new school buildings or additions to buildings, except in cities of the first and second classes. He makes rules and regulations for the examination of teachers, with the approval of the Regents; keeps in his office a record of all diplomas and certificates in force; and may annul, for cause, any teacher's certificate or diploma. He maintains a legal division for the decision of all appeals on school questions, and his decisions have the force of law. He designates all academics, union free schools, and high schools in which teachers' training classes may be organized; prescribes the conditions of admission and the course of instruction; makes rules and regulations for their government; and approves the money grants to such schools. He apportions, according to law, the state aid to common schools, academics, high schools, libraries, and industrial schools, and in making appointments is allowed certain discretion. He may withhold one half of the state money from the district which fails to enforce the compulsory education law. The Indian schools of the state are under his sole jurisdiction. He is responsible for all books and records in his department, and also for the proper administration of the offices. He is assisted in his work by three assistant commissioners, the directors of the state library and the state museum, and nine chiefs of divisions, as follows: administration, attendance, educational extensions, examinations, inspections, law, school libraries, statistics, trade schools, and visual instruction.

There are no county superintendents in New York. In their place we find (beginning Jan. 1, 1912) district superintendents, elected by a small body of town school directors for five-year terms. Each town in each supervisory district of a county was to elect two persons, in 1910, to be known as school directors, one for three years and the other for a five-year term, and thereafter, as their terms expire, their successors are to be elected for five-year terms. These school directors, in 1911 and every fifth year thereafter, are to meet and elect the division superintendent, this being their sole duty. Women are eligible for the office, and the superintendent elected need not be a resident of the district or county.

The fifty-seven non-city counties of the state are divided, according to size, into 207 superintendency districts, as follows:—

- 1 district to the county, 4 counties.
- 2 districts to the county, 8 counties.
- 3 districts to the county, 18 counties.
- 4 districts to the county, 13 counties.
- 5 districts to the county, 7 counties.
- 6 districts to the county, 4 counties.
- 7 districts to the county, 2 counties.
- 8 districts to the county, 1 county.

No city or district employing a superintendent of schools is to be included in a superintendency district. These districts are to be con-

tiguous and compact, and no town is to be divided in their formation. The salary of each district superintendent is \$1200, paid by the state, with \$300 for traveling expenses, and as much more as the supervisors of the towns in the districts see fit to add. Each superintendent must hold a state teacher's certificate, and a special certificate in the supervision of agriculture, and he must devote his entire time to the work of supervision. He succeeds to the powers and duties of the school commissioners. These powers and duties are to keep a record of the boundaries of the school districts; to conduct local institutes; to appoint district trustees, in case of a vacancy, if the district fails to elect; to inspect any teachers' training classes in his district, and report on the same to the Commissioner of Education; to meet with the school trustees of the district, and to advise with them as to details of school management; to administer oaths, and to transmit testimony in appeal cases to the Commissioner of Education; to act for another district superintendent on request, or when directed to do so by the Commissioner; to examine and license teachers, to conduct examinations for the State Department, and to revoke the certificates of teachers in his district, for cause; to make investigations and report to the Commissioner of Education, as requested; and to act subject to the rules and regulations of the Commissioner. He may order repairs to any schoolhouse up to a cost of \$200 or to furniture up to \$100; may order nuisances abated; and may condemn schoolhouses. If a school is condemned, a district meeting is called, at which the district superintendent presents an estimate of needs. This estimate cannot be scaled down by the meeting to exceed 25 per cent, and, if no district action is taken within thirty days, the trustees must proceed to build a building, which must cost not less than 75 per cent of the estimate presented by the district superintendent. He may organize new school districts, and may dissolve or consolidate districts, as educational interests seem to require, though an appeal from his decision may be taken to the Commissioner of Education.

Each county is also divided into a number of towns, and these in turn into school districts. For each town there is a representative supervisor and a town clerk, both of whom possess some educational functions. The supervisor has control of any gospel or school lands or funds possessed by the town; receives all school moneys due to his town from the county treasurer, and pays out the same on orders from the districts; if the districts elect a treasurer, he then turns the money over to him; and he acts as a general supervisor of the different school districts in all money matters, making an annual report on finances to the county treasurer. The town clerk acts for the town in all school matters as an interme-

diary between the district superintendent and the school trustees of the districts, seeing that notices are given; reports made, records preserved, etc.

A town unit of school administration has not yet been evolved, and town consolidation of schools has not as yet been begun, except in so far as districts are allowed to contract for the education of their children instead of maintaining a school themselves, and except as a town may be a city or a union free school district. Otherwise, the towns are divided into a number of school districts, each with its own officers. A district may have one trustee, elected annually, or three trustees, elected for three-year terms, one going out of office each year. A district also has a district clerk and a district collector, and it may, in addition, elect a district treasurer to take charge of its funds and pay all bills. These officers are elected in annual meeting for one-year terms. The trustees are to insure and care for the property; make up the tax lists for collection; purchase or lease sites, and erect buildings, as directed; make repairs and abate nuisances; employ teachers; prescribe the studies to be taught; make rules and regulations, issue orders on the funds for salaries and other bills; establish branch schools, when needed; and make annual and other reports to the division superintendent and to the annual district meeting. An annual meeting is held in May in each district, and special meetings may be called. The meeting hears the reports of the district trustees; elects a new trustee and the other school district officers; designates and changes all textbooks; can select a schoolhouse site; and must vote, by ballot or by aye and nay, all taxes for maintenance, library, schooling elsewhere, high school tuition, repairs, or new buildings. Women may vote on the same terms as men at such meetings.

In any district, on petition of fifteen inhabitants, or on petition of fifteen inhabitants in each of two or more contiguous districts, a school meeting may be called to vote on the question of forming a union free school district and electing a board of education. This is an old institution in the state of New York, and has rendered valuable service in providing free schools and secondary education. Similarly, a union free school district may call a meeting to dissolve into its original districts, though in this case, the district superintendent may veto the proposal. Each free school district has a board of education of from three to nine, one third going out of office each year. If there are 300 children in the district, an election by ballot takes the place of a school district meeting election. If the union free school district is coterminous with a city, the city treasurer acts as treasurer of the district, but if the bounds do not coincide, the school district elects its own treasurer.

Boards of education in all free school districts have, in addition to the powers of district trustees, the power to adopt textbooks; to establish an academic department (high school), kindergartens, or a night school; to provide medical inspection; appoint a truant officer; and, if the district has 5000 population, they may appoint a superintendent of schools. Instead of establishing a high school, the district may vote to adopt an existing academy as its academic department. The board must present to the annual district meeting, or to the proper city authorities, if a city, an annual estimate of the money needed for teachers' salaries, contingent expenses, and other items. The voters, or city authorities, cannot decrease the amounts for teachers and contingent expenses, but may decrease or increase all other items.

An important part of the school system of the state of New York is the large cities, most of which operate under special charters, and maintain extensive and important school systems. Three of these, Albany, Buffalo, and New York City, are described in special articles (*q.v.*). About 60 per cent of the people of the state reside in cities of over 100,000 inhabitants, and 52 per cent are in the city of New York.

School Support. — The permanent common school fund and the literature fund for aiding academies each produces but relatively small amounts, and the total value of all permanent school funds in the state is only a little over nine millions of dollars. The income derived from these forms but a small part of the annual state appropriations, and bears no relation to the rapid increase in the cost of education. During the past twenty years the cost of maintaining schools in the cities has quadrupled, and doubled in the towns. In lieu of state taxation, annual appropriations for education are made by the legislature. These are constantly increasing and are calculated in advance so as to meet legal needs. The state appropriation for the maintenance of common schools is now about five millions annually, and this is apportioned in such a manner as to divide it about equally between the cities and the towns. As the cities spend about three times the total amount spent by the towns, the state grants pay about one twelfth of the cost of education in the cities and about one fourth of the cost of the towns. The balance is paid by local taxation in the school districts, there being no county school taxation in New York. This system of distribution is the result of a wise but somewhat complex plan for the apportionment of school money, in which the teacher is made the unit and in which poor and small districts are given an initial advantage over large and wealthier ones. Orphan asylums may share, under certain conditions. Every city or district having over 5000 inhabitants and employing a superintendent of schools,

also receives a superintendent's quota of \$800. The state appropriation for academies, high schools, and libraries is now about three quarters of a million dollars annually, and this is apportioned in a still more complex manner. In 1910, 10 per cent of this appropriation was given as a school quota, 25 per cent was for books and apparatus, 35 per cent was for the instruction of non-residents, and 30 per cent was given on the basis of average daily attendance. Academies and high schools maintaining an approved course for the training of teachers receive \$700 additional, and the city training schools are paid on the basis of average daily attendance. The salaries of district superintendents and the expenses of Indian schools are paid by the state. In addition, the annual appropriation for salaries, traveling and miscellaneous expenses, examinations, and books for the state educational department now exceeds \$600,000.

Educational Conditions. — The state has many cities and a very cosmopolitan population. Two thirds of the total population live in cities of over 8000 inhabitants, while only one fifth live in country districts. A little over one fourth, 29.9 per cent, of the total population is foreign born, and in the cities the percentage is much higher. The city school systems are well developed and offer good instruction. The compulsory education and child labor laws are good, and the school census law for metropolitan cities, which may be adopted by any other city, is one of the best in the United States. But 1.5 per cent of the total population is of the negro race, though in the large cities this percentage runs much higher. No exclusion from any school is permitted on the basis of race or color, though the inhabitants of any district may provide separate schools for those of the colored race. Since 1895 the money spent for public schools has increased rapidly, being two and a half times as much in 1910 as in 1895. The total value of the public school buildings has trebled in the same time, while the average value has a little more than doubled (\$2618 in 1910). During the same period the total school enrollment has increased 22 per cent and the number of teachers employed, 57 per cent. The rural schools have made much less progress than the city schools during the past two decades, perhaps in part due to the strength and conservatism of the district form of control. The consolidation of schools and the transportation of pupils has as yet made no marked headway in the state, though some 800 districts now employ the contract system, in whole or in part. There are still 10,565 school districts (1910) in the state, as opposed to 11,089 fifteen years ago, and 11,262 twenty-five years ago. The school term has remained nearly stationary at an average of about thirty-five weeks per year for the past twenty years. Recently it has advanced to thirty-seven

weeks. A state syllabus (course of study) covering the eight years of the elementary course was issued in 1904, and a revision, covering only the first six years, was issued in 1910. School libraries, traveling libraries, the division of visual instruction (for the loan of pictures, charts, lantern slides, and specimens to the schools), and the extension division are marked features of the New York school system and do much to increase its efficiency. (See MUSEUMS.)

Teachers and Training.—Of the 45,076 teachers employed in 1910, 60 per cent were employed in the cities. Of the total teaching body in 1910, 7 per cent were college and professional school graduates, 20 per cent graduates of normal schools, 28 per cent graduates of teachers' training classes, 6 per cent held state teachers' certificates, and 37 per cent had been certificated by the local authorities. All new teachers for elementary schools must be experienced or have had professional training, and the equivalent of a high school education. All examinations for teachers' certificates are now conducted by the division of examinations of the State Education Department, under rules and regulations prescribed by the Commissioner of Education, and with the approval of the Regents. State normal school diplomas and state certificates from other states may be accorded equal privileges in New York. For the training of future teachers, the state maintains ten state normal schools, the Albany normal college, and, in addition, extends aid to ninety-five high schools and academies and to fifteen cities for offering teachers' training courses. Teachers' institutes, which have previously been under the state department and in charge

of institute conductors, are to be discontinued after 1911, the new district superintendents being expected to conduct local teachers' meetings on Saturdays, or at other times when the schools are not in session.

Secondary Education.—The development of secondary schools has been especially marked since the passage of the Horton aid law in 1895, the number of academies having increased from 131 to 167, and the number of high schools from 373 to 702 since then. The number of students and teachers has also undergone a rapid increase. In addition, 199 private high schools made reports in 1910. Since 1895 the Regents' academic examinations have been based on the completion of a four-year high school course. Syllabi (courses of instruction) are issued by the state department and inspections of work are made, though there has been a tendency to decrease the rigidity of the state requirements since the unification.

Higher Education.—The state maintains no state university, in the sense that the western states do. It has been proposed to evolve the University of the State of New York into a graduate institution for the study of history, politics, economics, education, and science (Sherwood); to evolve Cornell University from the position of a semi-state university to that of a real state university; and to evolve, instead, a series of municipal universities, extending across the state (Draper). The land grant for a college of agriculture and mechanical arts (law of 1862, 990,000 acres) was given to Cornell University, at Ithaca. In return for this, the university receives free of tuition one student each year from each legislative assembly district in the state,

the appointments being awarded on the basis of competitive examinations. The state has also recently established three additional schools of agriculture, for elementary and practical investigation and instruction, the work to be coordinated with that of Cornell University. These are at St. Lawrence University, in northeastern New York (1906); at Alfred University, in western New York (1908); and at Morrisville, in central New York (1908).

The work of providing higher education for the state of New York is carried on by a number of institutions, on which separate articles will be found, as shown on the previous page.

Special Education.—The state maintains sixteen special institutions for the care and education of the deaf, dumb, blind, feeble-minded, and for truant and incorrigible children, and makes arrangements with a number of other institutions of a semi-private nature, but open to state visitation and inspection, for the care of some of its deaf, dumb, and blind. Orphan asylums are also granted, on inspection and approval, teachers' quotas in the annual state apportionment of school money. A few of the cities also maintain truant and reformatory schools, though the city truant or parental school has not as yet been much developed by the cities of the state.

NEW YORK TEACHER.—See JOURNALISM, EDUCATIONAL.

NEW YORK UNIVERSITY.—New York University was founded in 1831 through the influence of a group of men in New York City

who conceived the idea of a university that should serve all classes of people and all professions. The plan of the founders contemplated a college, engineering school, school of law, school of medicine, school of education, school of agriculture, and graduate school. The first Chancellor was the Rev. James M. Matthews, D.D. The site at Washington Square was acquired in 1833 and the cornerstone of the first university building was laid in the summer of that year. The institution opened with the regular college courses and with special courses in mathematics and science for engineers. The law school was established in 1835 and the medical college in 1839. Through lack of funds the institution did not progress beyond these beginnings for the first half century of its history. This early period was rendered distinctive however by the ability and achievement of members of the University's faculty. Professor Samuel F. B. Morse invented the recording telegraph and Dr. John W. Draper perfected Daguerre's system of photography and took the first picture of the human countenance within the University walls during this period; while Dr. Valentine Mott as dean of the medical college and Benjamin Butler as principal of the law faculty lent luster to the professional schools.

The expansion of the institution into its present organization of 10 faculties, 370 instructors, and 4400 students, has taken place within the past twenty-five years under the sixth Chancellor, Dr. Henry Mitchell MacCracken. Under his efficient administration the magnificent site at University Heights was acquired in 1891 and was gradually increased until it reached its present extent of forty acres. The three original schools have been reorganized and new schools founded until now the instruction is carried on at four different centers as follows:—

At University Heights—The College of Arts and Pure Science (1831), the School of Applied Science (1862) and the Summer School (1895). At Washington Square—The Graduate School (1886), the School of Pedagogy (1890), the School of Commerce, Accounts, and Finance (1900), the Washington Square Collegiate Division (1903) and the Woman's Law Class (1890). At First Avenue and Twenty-sixth Street—the University and Bellevue Hospital Medical College (1841). At 141 West 54th Street, the New York American Veterinary College (1899).

This lack of concentration of all the schools at one common center is not the result of chance but is due to the policy of the University to carry its educational facilities to the people and to offer it at centers that are most advantageous and most accessible. As a logical outcome of this policy the University established the extra-mural division in 1909, the first department of its kind in America,

and this division now gives University instruction at various centers outside the University walls.

The corporation of the University is the Council, a self-perpetuating body of thirty-two members, one fourth of whom go out of office annually. The Women's Advisory Committee, consisting of women appointed by the Council, was organized in connection with the founding of the School of Pedagogy in 1890 and has done effective service in the University's work for women, aiding in the raising of endowment, furnishing of equipment, and the establishing of new courses. The University Senate, consisting of the chancellor, the deans of the schools, and one professor from each faculty, takes action regarding matters common to all the Schools and makes recommendations thereon to the University Council. The administrative officers are five in number, viz.: The chancellor, the syndie, the bursar, the registrar, and the secretary to the chancellor. Each faculty has its dean and secretary. The dean is the medium of communication between the faculty of his school and the chancellor; the chancellor is the medium of communication between the several faculties and the Council. Dr. Elmer Ellsworth Brown, formerly United States Commissioner of Education, is Chancellor. G. C. S.

NEW ZEALAND, EDUCATION IN. —

This system can best be understood when it is recollected that the country, now a federated dominion, was formerly divided into provinces under separate governments. This was the case from 1853 to 1876. In each of the principal provinces, between the years 1855 and 1857 a system of public elementary education was established. The schools were conducted by local committees and a central board at each provincial capital, and were variously supported by treasury grants, fees, charges on householders, donations and rates on property. The provincial system of public education survived the provinces themselves, which were abolished in 1876; but in 1878 a system, free, compulsory, and secular, was established, although provincial boards and inspectors were and are still retained.

The present system of administration of public instruction in New Zealand is described in an official account. "The Dominion is divided, for purposes of primary education, into thirteen education districts, generally coextensive with the old provinces or with subdivisions of them. The education districts are subdivided into a large and increasing number of school districts, in each of which there is a School Committee of five to nine members elected annually by the householders. In each education district there is an Education Board of nine members, elected three every year for terms of three years by the members of the School Committees. Under an Act

of 1905 every education district is divided into three wards, each of which returns three of the nine members of the Board. Subject to general supervision and control by the Board, and to inspection by the Board's Inspectors, the Committee has the management of school business within the school district. The Board appoints and removes teachers, but only after consulting the Committee.

The Education Department, which is presided over by the Minister of Education, is charged, in the first place, with the general supervision and control of the system of primary instruction, and, further, with the development and extension of a general system of secondary and technical instruction. Also with the direct control of the system of public school cadets, of the schools for children of the Maori race, the special schools for deaf and for mentally defective children, and the schools for destitute, neglected, and criminal children. Incidentally it has the administration of the Act for the protection of infant life. It takes an active interest in the education of the blind. It distributes the grants made by Parliament to public libraries. In order to provide suitable reading matter for the children in the public schools the Department prepares and issues a free School Journal. The Minister is required by statute to report to the Governor every year on the progress and condition of public education in the Dominion.

The precise manner in which the provisions of the various statutes that relate to the public primary schools shall be carried out is fixed from time to time by regulations made by the Governor in Council. Among the matters so controlled by regulation are the following: Attendance registers and returns, the authorization of class books, the inspection and examination of schools, teachers' certificates, training colleges for teachers, pupil-teachers, examinations for scholarships tenable at secondary and technical schools, for entrance into the public service and for promotion in it, manual and technical instruction, scholarship, public-school cadet corps, staffs of schools, and salaries of teachers, the payment of grants to Education Boards and the auditing of Boards' accounts.

One of the principal functions of the Department is to distribute to the Education Boards and other educational authorities, in the manner prescribed by law, the grants voted by Parliament for the salaries of teachers and for the maintenance of primary schools and training colleges, and secondary and technical classes, and for the erection and repair of school buildings and for higher education.

The status and progress of public elementary education in New Zealand may be best illustrated by the following table compiled by the Education Department at Wellington, New Zealand.

NEW ZEALAND, EDUCATION IN

	1870	1906
Population, exclusive of Maoris	417,622	908,718
Public primary schools	730	1,847
Children on the school rolls	55,688	139,302
Teachers, male	648	1,314
Teachers, female	449	1,887
Pupil-teachers, male	82	153
Pupil-teachers, female	221	518
Total teaching staff	1,400	3,872
Inspectors	10	32

Of these 139,302 children on the rolls, 72,917 were boys and 66,385 were girls. The total expenditure of the education department on all accounts for the year ending the 31st March, 1907, amounted to £923,574.

The official account of primary education in New Zealand will show how the situation differs from that in the Australian states, where public education is supported and controlled by the state from the consolidated revenue, without any form of local control or support.

"From 1878 to 1901 the public schools were maintained mainly by a statutory grant out of the consolidated revenue of the colony at the rate of £3 15s. a year for every unit of the average daily attendance, supplemented by additional capitation allowances varying from 4s to 10s, and by grants averaging about £45,000 a year for the erection and maintenance of school buildings. During that time every Board had its own scale of staffs and salaries, and there was considerable inequality in the remuneration of teachers under different Boards. But 'The Public-School Teachers' Salaries Act, 1901,' fixed the relation of the number and the pay of the teachers in a school to the number of the pupils, and the Boards are now paid sums sufficient to cover the statutory salaries of their teachers; they also receive capitation of 11s. 3d. for general administration and local expenses, and 1s. 3d. for secondary scholarships, and variable smaller grants for other special purposes. Grants are also made for school buildings as before, but upon a much more liberal scale. About two thirds of the total income of the Boards is absorbed in the payment of teachers' salaries. The remainder forms the fund out of which the Board maintains its schools and other buildings, pays the salaries of its inspectors and of its office staff, and grants certain allowances to the committees for fuel, cleaning, and incidental expenses, and for school libraries. The fund at the disposal of a Committee may be supplemented by donations and subscriptions, and by fines recovered for truancy. The sums granted to the Boards in 1906 for all purposes connected with primary instruction amounted to a total of £668,440, which is equal to a capitation of £5. 9s. 7½d. on the average attendance."

NEW ZEALAND, EDUCATION IN

No fees are chargeable for primary instruction at the public schools. Neither members of education boards nor members of school committees receive any remuneration for their services.

The schools are open to all children between the ages of five and fifteen, and attendance is compulsory from seven to fourteen. The instruction is entirely secular, though religious instruction may, with the consent of the committee, be given in the school building out of school hours. The subjects of instruction are reading, writing, arithmetic, English grammar and composition, geography, history and civic instruction, moral instruction, nature-study and elementary science, drawing, vocal music, the principles of health, physical and military drill, handwork, and, for girls, needlework.

Free passes by rail are given to pupils not over fifteen years of age traveling to attend schools for primary instruction, to pupils not over nineteen years of age who are holders of free places at secondary schools, to pupils on the rolls of primary or secondary schools traveling to attend classes for manual or technical instruction at centers specially equipped for the purpose, and, without restriction of age, to holders of free places at technical schools. Commutation and season tickets at liberal rates are given to other attendants at secondary and technical schools.

There is no public institution in the Dominion for the instruction of children under five years of age, but free kindergartens have been established by private promoters in some of the largest towns. On attendance at such schools capitation is, by special arrangement, payable by the Government at the rate of £2 per annum per unit of average, subject to certain conditions which provide for a minimum limit in salary payments, and further require an equal sum to be furnished from other sources, *e.g.* from donations and subscriptions.

In the field of secondary education, there are twenty-eight high schools or colleges in the dominion, which in almost every case derive a part of their revenue from public reserves. At the end of 1906 these schools employed 154 resident and 54 visiting teachers, and had as pupils 2528 boys and 1742 girls. Schools for boys and girls are usually separate. Fees averaging eight to ten guineas a year are charged, but many free scholarships are allowed. In addition to these secondary schools of the more ambitious kind, there are also more than sixty public schools which have free high school departments.

Manual and technical instruction is advancing rapidly, the total government expenditure in this direction in 1906 being £63,255. There is a flourishing cadet system in connection with the public schools. There is a superannuation fund for teachers, to which teachers may subscribe if they please from 8 to 10 per cent of their salaries, in return for which they

NEW ZEALAND, UNIVERSITY OF

are entitled to a pension or superannuation amounting to one sixtieth of their total salaries paid during the years in which they have been contributors to the fund.

Higher education is conducted by a chartered University of New Zealand, which is an examining body to which four other institutions are affiliated, namely, the University of Otago, founded in 1869, at Dunedin; Canterbury College, founded in 1876, at Christchurch; Auckland University College, founded in 1882, at Auckland; and Victoria College, founded in 1897, at Wellington. By a curious system the University of New Zealand sends its final examination papers for degrees to be examined in the universities of the United Kingdom.

Native schools to the number of 100 are provided for the benefit of the Maoris in places where no public schools have been established by the boards. In 1906 these schools were attended by 2275 boys and 1899 girls. In 10 per cent of these children European blood predominates, and 10 per cent were Europeans.

Among the other public educational institutions of New Zealand are numbered an institution for the blind, another for the deaf and dumb, many public libraries subsidized to the extent of £3000 a year, and seven government industrial schools for the maintenance and education of destitute, neglected and criminal children. In 1906 there were on the books of these industrial schools 2075 children, only 681 of whom were resident, while others boarded out or were at service. Fuller information may be obtained from the official account of the *Education System of the Dominion of New Zealand*, issued by the Department of Education at Wellington. P. R. C.

NEW ZEALAND, UNIVERSITY OF. —

See NEW ZEALAND, EDUCATION IN.

NEWBERRY COLLEGE, NEWBERRY, S.C. —

A coeducational institution founded in 1832 at Newberry, S.C., as the Classical and Theological Institute of the South Carolina Synod. In 1856 the College obtained a charter with power to confer degrees and was removed to Newberry. From 1868 to 1877 the College was located at Walhalla, S.C. Preparatory and collegiate departments are maintained. The requirements for admission are eight units. The degrees of A.B. and A.M. are conferred. In 1912 the faculty consisted of fourteen members and the students numbered 255.

NEWCASTLE COMMISSION. — See.

PARLIAMENTARY EDUCATION COMMISSIONS; ENGLAND, EDUCATION IN.

NEWCASTLE - UPON - TYNE, ARM-STRONG COLLEGE, ENGLAND. — An institution founded in 1871, as the College

NEWFOUNDLAND, EDUCATION IN

of Physical Science, "to promote the education of persons of both sexes and the study and advancement of science, philosophy, literature, and the fine and mechanical arts or other kindred branches of learning." The College is an incorporated Society, registered under the Companies Acts, and all subscribers of certain amounts are styled Governors. To these are also added the peers and members of Parliament of the local counties. The College has ten representatives on the Senate of the University of Durham of which since 1909 it is an integral part. The following faculties are maintained: pure science; applied science; arts; letters. The College has a Marine Laboratory at Cullercoats, and directs the Northumberland County Council Agricultural Station. A Day Training Department is also maintained in connection with the Board of Education. Work is given in day and evening classes to students over sixteen who have passed the matriculation examination of Durham University (*q.v.*) or some equivalent standard, if they wish to study for a degree. The College itself does not grant degrees, but the degrees of Durham University in science, letters, and in engineering are open to its students. The College grants diplomas in agriculture, engineering, naval architecture, and mining. The chemical, physical, and engineering laboratories, which are among the finest in England, give ample opportunity for practical work. The College receives grants from the Durham University, from many neighboring city and county councils, which also maintain many scholarships and prizes at the College, and from the Treasury, the Board of Education, and the Board of Agriculture and Fisheries. The enrollment of students in 1910 was 600 in the day and 475 in the evening classes with a faculty of sixty-one members.

NEWELL, McFADDEN ALEXANDER

(1824-1893). — Normal school principal and state superintendent; was educated at Queen's College, Belfast, and Trinity College, Dublin. He was professor in Baltimore City College (1848-1850), in Lafayette College (1850-1854), principal of the state normal school of Maryland (1865-1868), and state superintendent of Maryland (1868-1893). He was the author of a series of school readers.

W. S. M.

NEWFOUNDLAND, EDUCATION IN. —

The development of education in Newfoundland is similar to that of the eastern provinces of Canada (*q.v.*). The present system was organized by acts of 1874 and 1876, which

rendered it completely denominational. The public schools are in charge of three separate boards representing the three religious denominations: Methodist, Episcopalian, and Roman Catholic. The governor in council has power to appoint in each educational district a board of five or seven members of the respective denominations, on which the senior of superior clergymen resident or officiating in the district shall be one, to manage and expend all moneys, etc. Such boards in St. John's, and in districts in which are superior, or high, schools, may consist of nine members. Vacancies occurring by death, resignation, or absence from the colony for twelve months may be filled by the governor in council. Similar boards are appointed in like manner for the four colleges, but the nomination of members is with the respective denominations. Each denomination has a general superintendent of education to which the corresponding boards make their annual reports.

The education boards have control of their respective schools, appoint the teachers, determine the salary, tenure, etc. The course of instruction in public schools is arranged for six grades or standards, sectarian teaching is allowed, but the rights of dissenting minorities are protected by a conscience clause in the school law. By the act of 1874 \$40,000 was provided for schoolhouses and school property and arrangements made for subdivision of property on an equitable basis, which was in due course accomplished without difficulty. By the 1876 act \$88,252 was annually provided for all purposes, which amount has been increased, from time to time, according to increase in population. The government grant is divided among the school boards on the basis of a specified rate per capita of the attendance in their respective schools. The attendance at board schools in 1907 was 48,311 distributed as follows: Church of England, 14,983; Roman Catholic, 14,721; Methodist, 13,092; others, 1015. The total expenditure, including government grants and fees, was \$281,655. Additional grants are made in aid of poor districts, for high schools, and for the support of colleges.

The high schools prepare pupils for admission to the colleges, in which provision is made for teaching advanced classes in ordinary commercial subjects, in Latin, Greek, French, German, algebra, geometry, mensuration and land surveying, chemistry, magnetism and electricity, free-hand and geometrical drawing, trigonometry and navigation, shorthand, music, and school management. In fact the colleges perform the double function of business colleges and classical colleges. They are all under government inspection, and reports of their condition and progress and a detailed account of income and expenditure must be transmitted by their respective superintendents

to be laid before the legislature, in accordance with prescribed forms. Students who complete the prescribed courses are prepared for matriculation in the Dominion universities.

A. T. S.

NEWMAN, JOHN HENRY (1801-1890). — Divine, and educational writer, born in London, 1801, the son of a banker said to have been originally of Dutch extraction and possibly of Jewish descent. His mother belonged to the Huguenot family Fourdrinier. He was brought up from a child to take great delight in reading the Bible. At the age of seven, he was sent to a well-known private school kept by Dr. Nicholas at Ealing. In his childhood the *Waverley Novels*, then appearing, and Scott's poetry had a great influence upon his imagination, which dwelt much upon magical powers, talismans, and other mysterious influences. At fourteen he read Tom Paine's *Tracts* against the Old Testament and found pleasure in thinking of the objections contained in them. He also read Hume's essays and remembered copying out some French verses against the immortality of the soul and saying to himself, 'How dreadful, but how plausible.' In 1816 a great change of thought took place in him and he fell under the influence of the Christian faith, receiving into his intellect impressions of dogma never afterwards effaced or obscured. Calvinist preaching and sermons helped in this conversion.

Newman went into residence at Trinity College, Oxford, June, 1817, becoming a scholar in 1818. In 1819 his father's bank stopped payment, and in the same year he took a Second Class in the Final Schools. After graduating B.A. Newman took some private pupils in Oxford and was elected a Fellow of Oriel College, April 12, 1822. At Oxford Newman came under the influence of John Keble, Hawkins, Whately, and Richard Hurrell Froude. In 1830 he definitely broke with the evangelical party and abandoned Calvinism. As a tutor of Oriel his mind was turned much to the theory and practice of education, the intimate connection of which with religious belief he strongly maintained. Newman's first public writing on education is found in his review of the works of John Davison (1744-1834), Fellow of Oriel College. During a visit to Sicily, 1833, Newman nearly died of fever. On his homeward journey in an orange boat, between Palermo and Marseilles, he wrote *Lead, Kindly Light*. The years 1833-1845 were full of momentous controversy on spiritual questions, ending in his reception into the Roman Catholic Church at Littlemore, near Oxford, October 9, 1845. After a visit to Rome he returned to England in 1847 with a commission from Pope Pius IX to introduce into England the use of the Oratory founded by St. Philip Neri, whose beautiful character and educational devotion especially attracted

him. He established the Oratory in Birmingham and resided there for the rest of his life. In 1854 he went, at the invitation of the Irish Roman Catholic Bishops, to Dublin as Rector of the then recently established Catholic University. The University was, however, a failure, partly through lack of State recognition and partly through Newman's own incapacity for organization. But his experience at Dublin flowered in the publication of his *Discourses on University Teaching*, issued subsequently under the title of *The Idea of a University Defined and Illustrated*. In these discourses occurs the famous passage in which Newman says that if he had to choose between two University courses, one non-residential but intellectually exacting, the other residential but intellectually disorganized, he would without hesitation give preference to that University which provided no teaching but brought together into personal companionship "a multitude of young men keen, open-hearted, sympathetic, and observant, gaining for themselves new ideas and views, fresh matter of thought, and distinct principles for judging and acting day by day. Such a youthful community embodies a specific idea, . . . administers a code of conduct, . . . furnishes principles of thought and action. It gives birth to a living teaching . . . which in course of time takes the shape of a self-perpetuating tradition or a *genius loci*, . . . which haunts the home where it has been born and which imbues more or less and one by one every individual who is successively brought under its shadow" (Discourse VI). The school for boys conducted at the Oratory in Birmingham under Newman's presidency has done educational work of high value. In 1879 Newman was created Cardinal, with the title of St. George in Velabro. He died at Edgbaston on August 11, 1890. M. E. S.

NEWMAN, SAMUEL PHILLIPS (1797-1842). — Principal of one of the first American normal schools; was graduated at Harvard College in 1816. He was a private tutor for two years in Kentucky, and from 1818 to 1839 he was a professor in Bowdoin College. He was elected principal of one of the first of the Massachusetts normal schools organized by

Horace Mann in 1839. The school was located at Barre but later removed to Westfield. This post he held until his death. His publications include a rhetoric, which passed through sixty editions, a textbook on political economy, and a series of school readers.

W. S. M.

NEWMHAM COLLEGE, CAMBRIDGE, ENGLAND. — An institution for the higher education of women. In 1871 Miss A. J. Clough (q.v.) took a house at Cambridge for five women students who wished to attend lectures there. The number grew rapidly, and in 1875 Newnham Hall was opened. Through the combined efforts of the authorities of Newnham Hall and the Association for Promoting the Development of Higher Education for Women (f. at Cambridge in 1873) Newnham College was established in 1880. The College now comprises the following buildings: Old Hall (1875), Sidgwick Hall (1885), Clough Hall (1889), Pfeiffer Building (1893), Kennedy Building (1906). The second of these Halls was named in honor of Professor Henry Sidgwick who played an important part in promoting the higher education of women and in the founding of the College. Like Girton, Newnham College has had a very prominent place in the history of women's education in England. The enrollment of students in 1910-1911 was 213.

See WOMEN, EDUCATION OF.

NEWSPAPERS AND PERIODICALS, COLLEGE AND SCHOOL — More than 400 newspapers and periodicals are regularly issued at colleges and universities in the United States. If to this number there be added the number of newspapers and periodicals issued by the high and elementary schools and the number of high school, college, and university yearbooks or annuals, which are more or less journalistic in character, the total number would exceed a thousand. The list of publications includes dailies, semi-weeklies, weeklies, monthlies, bimonthlies, and quarterlies. It includes periodicals which are devoted to literature with no admixture of news, and periodicals which are devoted entirely to news, others that publish news and literature, and yet others, treating the lighter side of college life, that are devoted to humor. Many of these publications are illustrated. Most of them are financially profitable. They are to the undergraduate world what the daily or weekly newspaper is to the world outside the colleges. They give the news of the college campus and comment upon it.

The college or school newspaper is generally issued by the students, under some form of faculty supervision or control. In a few cases it is issued directly by the faculty representing the institution. The students, through their own organization, incorporated or otherwise,

select the editors and reporters. In most institutions, the editorship of the newspaper or magazine is regarded as one of the highest honors which the undergraduate may attain. Often the selection of associate editors and reporters is by competition, and there are many more applicants than there are positions to be filled. In some institutions, academic credit is given for such activities; and in others the higher editorial positions usually are accompanied by special society or college honors.

The college publications are not new in America. The earliest appeared at Dartmouth with Daniel Webster as editorial writer. The college daily came later. The Cornell *Daily Sun* was the first issued by an incorporated organization. Now daily newspapers are published at all the larger universities.

Students who plan to enter journalism (*q.v.*) or literature usually seek positions on college journals. Where courses are given in journalism the college journals afford a laboratory for students taking such courses.

W. W.

England. — There are few secondary schools in England that cannot boast of at least one official school magazine, published as a rule once a month during the school year. From time to time other sheets raise their diminished heads, either as representatives of special interests, of a special group, or of some form of the school. But these rivals rarely come to maturity, for not uncommonly they depend for their existence on the enthusiasm, lively but evanescent, of a few boys. Even the recognized school magazine frequently varies in quality, through the changing and shifting character of its staff. As a general rule the school magazines in England are conducted almost wholly by a committee of masters and boys or of boys alone under the general and benevolent supervision of a master. The content and arrangement are in most cases the same: occasional notes, honors and distinctions, news of old boys, a poem or two (in modern or classical language, original or translated), a few articles by present or old boys, and reports of school activities (different school societies, and athletics). A charge is invariably made for the magazine. Many school efforts have been wrecked on this financial rock, but compulsory subscriptions or advertising matter have been called in to aid. Within recent years the school magazine has tended also to become the official organ of old boys' associations, and in this way the list of subscribers is substantially increased.

The history of school publications is recent, even in the oldest schools. Occasional efforts appear to have been made at the beginning of the nineteenth century to launch school papers but rarely with success. The causes are not far to seek; the cost of printing must have been high, and corporate school spirit as

it is now understood was perhaps only in the early stages of its development. But here and there boys who not infrequently made their mark later in the literary world would seek to give rein to their genius while still at school. At Eton the earliest recorded magazine was the *Microcosm*, edited in 1786 by George Canning, John Smith, Robert Smith, and John Hookham Frere. The next publication in 1804 was the *Minutiae*, of which thirty-four numbers were issued in twelve months. After an interval of a few years there appeared, about 1818, a number of manuscript publications, all of which were shortlived. In 1819 appeared perhaps the most famous of Eton magazines, the *Etonian*, in the management of which W. M. Praed was the leading spirit. Many of Praed's contributions attracted considerable attention. The *Eton Magazine*, which appeared in 1827, is notable mainly for the fact that W. E. Gladstone was one of the editors. After a desultory period of nearly thirty years another crop of ephemeral magazines appeared, the *Adventurer*, which lasted from 1867 to 1872, being the longest lived. Most of the publications, however, were hardly school magazines in the sense described above. They aped or imitated the literary reviews of their day and afforded for many years an opportunity for the boys to exercise their literary ability in the vernacular before English composition became a school subject. The first grammar school magazine—a record of school activities—was the *Eton College Chronicle*, which appeared in 1863 and has continued up to the present. At Harrow the first magazine, the *Triumvirate*, appeared in 1859; in 1863 its title was changed to the *Tyro*; in 1869 it was again changed to the *Harrovian*, and from 1883 to 1888 was published outside the school under the title *Harrow Notes*. In 1888 the magazine was again restored to the school, and since that time the *Harrovian* has been the recognized school organ. At Rugby the earliest publication was the *Rugby Magazine* (1835), mainly a literary work, followed ten years later by the *Rugby Miscellany*, containing essays and poems, giving occasional glimpses of school life and Arnold's work. The *New Rugbeian*, which appeared in 1858, ran through three volumes. Other ephemeral magazines at Rugby have been the *New Rugby Magazine* (1864–1865), the *T. V. W.* (1877–1878), the *Leaflet* (1883–1886), and *Subyl* (1890–1895). The *Meteor*, the first paper which claimed to be nothing more than a chronicle, appeared in 1867 and is still flourishing. At St. Paul's School, London, a magazine, *Hermes*, appeared before 1832, but little is known about it. About the same time (1831), showing how readily a stimulus works in school, appeared the *Pauline*, which died an early death, was revived for a short time in 1836, and again in 1882, since which time its existence has been unbroken. As in

other schools the *Pauline* has had to face upstart competitors, but these have not been able to survive the departure of their editors from the school.

It thus appears that the essential qualities of a newspaper are not the literary productions but the appeal to the generality; school news and full reports of school activities, liberally interspersed with the names of youthful aspirants to distinction, are the means to assured success. A few magazines of other prominent schools may be mentioned: *Charterhouse*, *Carthusian* (1872); *Shrewsbury*, *Sa-lopian* (1834, 1860); *Winchester*, *Wykehamist* (1866); *Westminster*, the *Elizabethan*; *Merchant Taylors*, the *Taylorian*; *Bedford*, the *Ousel*; *Bradford*, the *Bradfordian*; *Cheltenham*, the *Cheltonian*; *Clifton*, the *Cliftonian*; *Marlborough*, the *Marlburian*; *Manchester*, *Ulula*; *Rossall*, the *Rossallian*; *Sedbergh*, the *Sedberghian*; *Tonbridge*, the *Tonbridgian*.

NEWTON, SIR ISAAC (1642-1727). — One of the greatest of the world's mathematicians and physicists. He was born in humble circumstances, and as a boy was rather backward in his studies. He lived on a farm, and the surroundings were not conducive to serious study. He had an uncle who agreed to send him to college, and so he prepared for entrance and was admitted to Trinity College, Cambridge, in 1660. Within six years after entering the college he had proved the binomial theorem for the general case, laid the foundations of the calculus, and begun his great work on the study of the attraction of planets. Newton seems to have found the principles of the calculus in or before the year 1665. (See CALCULUS.) In 1667 he became a Fellow of Trinity College, and in 1669 he became Lucasian professor of mathematics, being then less than twenty-seven years old. His greatest works are the *Principia* (1687), *Optics* (1704), *Arithmetica Universalis* (1707), *Analysis per Equations Numero Terminorum Infinitas* (1711), *De Mundi Systemate* (1728), and *Optical Lectures* (1728, posthumous).

He also contributed many memoirs to the Royal Society from 1703 to the time of his death. He was knighted by Queen Anne in 1705. D. E. S.

NEWTON THEOLOGICAL INSTITUTION, NEWTON CENTRE, MASS. — An institution for the training of students for the Christian ministry in Baptist churches, founded in 1825. A course of three years

leading to the degree of D.B. is offered to students who have already some college degree or its equivalent. Women who intend to devote themselves to missionary work are admitted to the lectures. In 1907 the Gordon Bible and Missionary Training School of Boston, founded in 1889, was consolidated with the Theological Institution as the Gordon School. A summer school is also conducted by the Institution. The faculty consists of nine members and there is an annual enrollment of about seventy-five students.

NIAGARA UNIVERSITY, NIAGARA FALLS, N.Y. — An institution located on the New York bank of Niagara River, founded in 1856 and conducted by Priests of the Congregation of the Mission, a body of religious educators established in seventeenth century by St. Vincent de Paul. Chartered as the Seminary of Our Lady of Angels in 1863, the institution was erected into a college as Niagara University by the Regents of the State of New York in 1883. The physical plant includes a campus of 300 acres, a group of buildings, including a museum, scientific laboratories, auditorium, literary society parlors, and a library of 35,000 volumes. It offers full college courses, and, in addition, has a theological seminary. The President is Very Rev. Edward J. Walsh, C.M. E. J. W.

NICARAGUA, EDUCATION IN. — Nicaragua, the largest of the Central American Republics, extends over an area of 49,200 square miles and has a population of 600,000 (estimated, 1910). About one third of this population is comprised in 13 towns, of which the largest is Leon, the former capital, having a population of 62,500. The present capital, Managua, has a population of 34,872. It is the center of the country's activities and exercises wide influence through its daily papers, morning and evening issues. The mass of the population consists of aboriginal Indians, negroes, and mixed races. The Europeans and their descendants are estimated at less than 2000. The prevailing religion is the Roman Catholic, the entire country forming one diocese under the Bishop of Leon, a suffragan of the Archbishop of Guatemala. The country is organized in thirteen departments and two comarcas, each under its own executive who has independent management of its internal affairs. The president of the Republic is assisted by a cabinet of ministers, one of whom is charged with the interests of public instruction. His authority in this matter, however, is limited by the independence of the departmental chiefs. He may require reports from each department as a basis for the distribution of the government appropriations for schools, but beyond this he has little more than advisory functions.

In a recent report, the minister of public

instruction deplores the low condition of primary education in the Republic. Five times as many schools as have been provided, he declares, are required in order to meet the actual needs of the population. There are about 350 primary schools, enrolling 23,000 pupils or less than 4 per cent of the population.

For secondary instruction there are four subsidized schools; namely, for boys, three, situated respectively in Managua, Leon, and Granada, and a normal school for young women in Managua. These schools enroll about 900 pupils and for each the State pays at the rate of \$5 a month. Private secondary schools follow the same programs as the public, all non-classical. The course in the normal school includes methodology, pedagogy, Spanish, mathematics, zoology, botany, drawing, physical sciences, and singing.

Higher education is represented by two University faculties of law, and by a faculty of medicine and surgery. The law course is very comprehensive, including philosophy of law, civil, comparative, and constitutional law, criminal law and criminology, medical law, statistics, and academic courses in Spanish and American literature, in history and political economy. There is an agreement with the other Central American States by virtue of which degrees granted in any one of them are recognized in Nicaragua as of equal weight with its own. Possessors of degrees granted in foreign countries must pass a brief examination and prove the authenticity of their diplomas.

The chief educational influences now working in the Republic come from the increasing relations with the other Latin American States and with the United States, and the impetus thereby given to the commercial, agricultural, and mining industries of the country. An evidence of the growing desire for harmonious relations among the Central American States is afforded by the appointment of a committee to draw up a manual of civic instruction adapted to each one.

The national museum of commerce and industry at Managua illustrates the increasing interest in the conditions that make for economic prosperity.

NICOLAUS VON CUSS (NICHOLAS OF CUSA, NICOLAUS CUSANUS). -- A fifteenth century scholar and writer. He was born at Kues on the Mosel in 1401, and died

at Todi, in Umbria, August 11, 1464. One of his biographers has thus tersely summed up his position: "Nicolaus wished to be a medieval philosopher, but with more liberty; he was, without wishing it, a modern philosopher, but with more reserve." His name was Nicolas Chryps, and he was son of a humble fisherman. In the patois of the Mosel valley, Chryps is the same as the German Krebs (crab) and hence he is known also by the Latin name of Nicolaus Cancer. He was educated at Heidelberg, and went from that university to Padua where, in 1424, he took the degree of doctor of laws. Returning to Germany, he made his first legal effort at Mainz, lost his case, and thereupon determined to devote himself to theology and science. In 1436 he presented to the Council of Basel a plan for reforming the calendar. So successful was he in diplomacy that Eugene IV, Nicholas V, and Pius II employed him on important missions, and in 1448 Nicholas elevated him to the position of cardinal, a very rare honor for a German in those days. Because of this unusual fact, he was known in Italy as Cardinalis Teutonicus. His works relate to questions of theology and metaphysics, the reform of the calendar, to the principles and value of mathematics, and to similar topics. Although not himself a teacher, by his writings he exerted a powerful influence upon the teaching of his day. His works had much to do with leading Leonardo da Vinci to maintain the theory of the plurality of worlds.

D. E. S.

NICOLE, PIERRE (1625-1695). -- One of the most famous writers of Port Royal (q.v.). Among his more important works are: *Logique* (1662); *Essais de morale* (1671-), 25 vols., in the second volume of which occurs his *Traité de l'éducation d'un prince*.

NICOMACHUS. -- The greatest writer on theoretical arithmetic among those whose works appear in Greek. He, however, was not a Greek, but a Jew. He was born at Gerasa, 50 A.D., and died about 111 A.D. His work is not that of a great mathematician, but is rather a compilation of the knowledge common to teachers of the subject in his time. The object of the book is the study of the properties of numbers, particularly as they had been studied by the Pythagoreans for some centuries, and as they were being taught by the neo-Pythagoreans in his day. For example, he classifies numbers as odd, even, prime, perfect, and so on, and studies with some care the various polygonal and solid numbers. Ratios, proportions, and progressions occupy

considerable of his attention. From his work Boethius (*q.v.*) derived much of the material for his textbook on the subject, a book that for a thousand years was the classic in theoretical arithmetic. His work was edited by Hoche, in 1866. D. E. S.

NICOMEDES. — See GEOMETRY.

NICOTINE. — See TEMPERANCE, TEACHING OF.

NIEDERER, JOHANNES (1778–1843). — Swiss educator and one of Pestalozzi's assistants. Educated and trained for the ministry, Niederer heard of Pestalozzi's work about 1800, resigned his pastorate at Appenzell and joined Pestalozzi at Burgdorf, where he had special charge of religious instruction. In this field he showed exceptional ability. But he was interested also in language and literature and in the broader social and philosophical aspect of education. He became indispensable to Pestalozzi as adviser and collaborator in his writings, and edited much of the latter's work between 1807 and 1811. But with a scientific and philosophical mind such as he possessed Niederer was not suited to interpret Pestalozzi and later some of his additions and interpretations were repudiated. Niederer edited the *Wochenschrift für Menschenbildung* (1808–1812), *Das Pestalozzische Institut und das Publikum* (1811), *Pestalozzi's Erziehungsunternehmung im Verhältnis zur Zeitkultur* (1812–1813). The recall of Schmid, however, led to a breach between Niederer and Pestalozzi in 1817 which continued until the latter's death. In 1828 Niederer wrote *Pestalozzische Blätter*. Niederer's wife, Rosalie Kastenhofer, conducted the girls' school established by Pestalozzi at Yverdon and removed in 1827 to Geneva, where a seminary was also opened for the training of teachers. Mme. Niederer was the author of *Blücke in das Wesen der weiblichen Erziehung. Für gebildete Mütter und Töchter* (*Glances at the System of Female Education. For educated mothers and daughters*, 1828), and of *Dramatische Jugendspiele* (*Dramatic Games for the Young*, 1838).

NIEMEYER, AUGUST HERMANN (1754–1828) — German educator, born at Halle, a direct descendant of August Hermann Francke (*q.v.*), whose work he continued. His parents died while he was very young, and he was brought up by Frau Lystenius, a lady of great culture and refinement. He received his early education in the schools founded by his great-grandfather, and at the age of seventeen entered the University of Halle, where he

studied theology and philology. In 1775 he published his first work, *Charakteristik der Bibel*, which at once made his name known all over Germany. In this book he showed how to use the biblical characters for moral instruction. In 1777 he began his academic career at Halle; in 1779 he was made professor of theology, and in 1785 he was appointed one of the directors of the Francke Foundations. He infused new life into these institutions which had declined under his predecessor. In 1806, the university was closed by the order of Napoleon I, and Halle annexed to the Kingdom of Westphalia. Niemeier not only lost his position, but together with some other citizens of Halle was forcibly removed to Paris, where he had to remain for several months. On his return he succeeded in his efforts to have the University of Halle restored and was placed at the head of the institution with the title of Chancellor and Perpetual Rector. He resigned this position in 1815, but remained active in lecturing at the University and in the administration of the Francke Foundations until his death.

Niemeier's most important work is his *Grundsätze der Erziehung und des Unterrichts* (*Principles of Education and Instruction*, 1796; Ed. G. A. Lindner, Vienna, 1877–1878). It was highly recommended by such a competent authority as Herbart, who found in it "the whole summary of contemporary pedagogy and a broad and firm empirical basis for the theory of education." Up to the time of the author's death, nine different editions of this work had become necessary. F. M.

NIETHAMMER, FRIEDRICH IMMANUEL (1766–1848). — A German schoolman born in Beilstein, near Heilbronn, Württemberg, studied philosophy and theology at the University of Tübingen, then lectured at the University of Jena, where he became acquainted with Schiller, Goethe, and Fichte. In 1804 he was appointed professor of theology at the University of Würzburg, and in 1808 he was called to Munich to assist in the reform of the Bavarian gymnasias. In 1817 he became a member of the board governing the Protestant churches of Bavaria (*Oberkonsistorialrat*) and devoted the rest of his public activity to ecclesiastical affairs.

Niethammer is best known as the author of the essay *Der Streit des Philanthropinismus und Humanismus* (*The Conflict of Philanthropinism and Humanism*, Jena, 1808) in which he defended the claims of the classical studies against the realistic studies favored by the Philanthropinists (*q.v.*). F. M.

NIETZSCHE, FRIEDRICH WILHELM (1844-1900).—German philosopher born at Röcken, Germany. He received his preliminary education at Naumburg, and in 1864 entered the University of Bonn as a student of philology and theology, the latter of which he discontinued at the end of the first semester. After a year at Bonn he went to the University of Leipzig, where he spent the greater part of four years, and where he busied himself with philosophy as well as with philology. In 1869, upon the recommendation of the distinguished philologist Ritschl (*q.v.*), he was appointed to the professorship of classical philology at Basel; and the University of Leipzig at once made him a doctor of philosophy without a thesis or examination. The next ten years were devoted largely to the work of teaching. In 1879 ill-health forced him to resign his position and to go from one health resort to another. In 1889 he became hopelessly insane, and lived at his sister's home in Weimar until his death, August 25, 1900. His principal writings are *Die Geburt der Tragödie (The Birth of Tragedy)*, 1872; *Menschliches allzu Menschliches (Human all too Human)*, Vol. I, 1878, Vol. II, 1879 and 1880; *Also Sprach Zarathustra (Thus spake Zarathustra)*, first complete edition, 1892; *Jenseits von Gut und Böse (Beyond Good and Evil)*, 1886; *Zur Genealogie der Moral (The Genealogy of Morals)*, 1887; *Gotzendämmerung (The Twilight of the Idols)*, 1889.

Although Nietzsche's writings are classed under the general heading of philosophy, they do not belong there in any technical sense of the term. He did not write systematic treatises, but devoted himself to the construction of brilliant aphorisms, and thus could discuss in quick succession subjects widely separated from one another. During the years of his creative activity his standpoint underwent frequent changes, but everywhere there may be found one unifying principle. Nietzsche's philosophy is always a philosophy of culture, as it presents itself to the man of marked aristocratic tendencies. The central problem is that concerning the nature of the ultimate good. If life is worth living, what makes it so? What is the supremely valuable? During his first period Nietzsche found the justification of the world, if it has one, in the æsthetic concept of beauty; then his standard of valuation became positivistic and he subjected everything to the intellectual test, rejecting much of what is usually regarded as true; finally he came to question the validity of the concept of truth itself, and the only valuation left him is ethical in nature. Although the writings of the first and second period offer much that is interesting and suggestive, Nietzsche's most characteristic theories are to be found in the books published after 1882. In them he preaches a "transvaluation of values," condemning the present-day morality

as that of slaves and exalting all the qualities belonging to self-assertion. The ultimate reality in the universe and the chief good for the individual is the will for power. Nietzsche makes no attempt to show that all human actions and feelings are at bottom selfish. He admits the existence of disinterestedness and deplores it. All history and all social organization find their one justification in the production of a few great personalities, whose one aim is the attainment of power rather than of happiness. Egoism is not so much a fact as an ideal. Closely connected with the possibility of its realization is the doctrine of the Superman, which presents both mystical and evolutionary scientific elements. The Superman is related to man as man is to the ape; and man should be glad to give place to his own superior, the incarnation of the egoist's ideal. As a means to its attainment every kind of struggle and difficulty should be increased and intensified. "A good war sanctifies every cause."

Although during the entire course of his literary activity Nietzsche occasionally wrote upon the subject of education, always advocating cultivation rather than learning, his views have not met with much attention and present no great originality. His real influence, which has been almost unparalleled in his own country and in other parts of Europe, is due rather to his general position. He is the philosopher of revolt. He encourages opposition to religion, to the accepted morality, and to intellectual and social customs and traditions. Self-assertion is the first duty of man; and with this end in view, education must be so remade as to encourage rather than to stifle the few great personalities. How can we hope for a Cesare Borgia or a Napoleon, if we teach and enforce commonplace standards? G. N. D.

NOISE—Noises may be said to be blurred tones. They correspond to aperiodic vibrations, and are classified as simple and compound. A simple noise is due to a momentary and irregular set of vibrations, for example, a tap, a flick, a thud, a click, etc. A compound noise is made up of repeated simple noises, usually in connection with tonal elements, *e.g.* the hiss, the roar, the rumble, the rattle, the crash, and the murmur. Many of the laws of tone sensations apply also to sensation of noise. C. E. S.

NONCONFORMISTS IN EDUCATION.—See DISSENTERS IN EDUCATION.

NON-DIACRITIC METHOD.—In teaching reading and spelling, more particularly the former, diacritical marks have been much used in dealing with phonetic difficulties. Phonetic methods which depend upon the analysis and synthesis of sound units by means of syllables, phonograms, and word wholes, to the complete elimination of all artificial marks and symbols, have been called non-diacritic methods. They represent a naturalistic tendency in instruction which constantly finds increased acceptance among progressive teachers. H. S.

See DIACRITIC METHOD.

NON-EUCLIDEAN GEOMETRY

NON-EUCLIDEAN GEOMETRY.—The geometry of Euclid (*q.v.*) contained a certain postulate (sometimes known as the fifth postulate and sometimes as the twelfth axiom) to the effect that only one line could be drawn through a given point and parallel to a given line. The postulate read as follows: "That, if a straight line falling on two straight lines make the interior angles on the same side less than two right angles, the two straight lines, if produced indefinitely, meet on that side on which are the angles less than the two right angles." The postulate was apparently very unsatisfactory to Euclid himself, for he avoids using it whenever possible. Numerous efforts were made by his successors to prove it, but no really scientific attempts to investigate its validity were made until Saccheri (1773), an Italian Jesuit, endeavored to prove it by a *reductio ad absurdum*. In attempting to show the absurdities that would follow if the postulate were not sound, he really developed, without appreciating it, a body of theorems that would be valid if the postulate were not accepted. Lambert, in a posthumous work of 1786, questioned the validity of the postulate. A little later, Gauss (*q.v.*) became interested in the question, but not until after others had set forth the real problem involved did he seriously attempt to consider it. The credit of definitely asserting that the fifth postulate is not in the same category as the others, and of building up a geometry based upon its opposite, in other words a "Non-Euclidean Geometry," is due to Johann Bolyai (1802-1860) and Lobachevsky (1793-1856). Bolyai was a Hungarian mathematician, and his ideas on the subject appear in brief in a letter written when he was only twenty-one years of age, that is, in 1823. Lobachevsky (*q.v.*) was apparently working on the theory at the same time, and entirely independently of Bolyai. Bolyai committed his theory to writing in 1825 and published it in 1832. Lobachevsky did not publish his work until 1835. The subject first attracted widespread attention in the publication of Riemann's memoir in 1854, in which he distinguished two kinds of non-Euclidean geometry, namely, the Bolyai-Lobachevsky type and his own. To these Klein (1871) gave the names of Elliptic (Riemann's) and Hyperbolic (Bolyai-Lobachevsky's), Euclid's geometry being called Parabolic. In Euclid's geometry the sum of the angles of a triangle is two right angles; in the Hyperbolic geometry it is less than two right angles, and in the Elliptic geometry it is more. All three geometries are entirely self-consistent and are logically valid. Within the limited space in which we work there is no practical difference in results, but in the domain of abstract mathematics the various geometries lead to conclusions that are widely different. D. E. S.

See GEOMETRY; LOBACHEVSKY; PARALLELS.

NON-METHOD READERS

NON-METHOD READERS.—Reading books for children which are graded merely with reference to their literary content, disregarding phonetic and spelling difficulties, are called "thought" or "non-method" readers. H. S.

NORMAL ART SCHOOLS.—See **ART EDUCATION**.

NORMAL CLASS IN HIGH SCHOOLS.
—See **HIGH SCHOOL NORMAL CLASS**.

NORMAL COLLEGE OF THE CITY OF NEW YORK.—Established February 1, 1870, and received its charter from the state in 1888. Thomas Hunter, LL.D., was its first president. It is a college for women and grants the degree of A.B. upon the satisfactory completion of a four years' course of study. It is supported by the city of New York with annual appropriations, that for 1912 being approximately \$400,000. Tuition and textbooks are furnished without charge. Students must be residents of the city.

Admissions and graduations are made twice a year. Candidates for admission must present fifteen units. The curriculum is arranged according to the elective group system and provides strong optional courses in education for those students who desire to enter the profession of teaching in either secondary or elementary schools. The equipment of the College is being renewed, and new buildings are being erected at a cost of \$2,500,000. The students number about 1250. The teaching staff comprises thirteen professors, ten associate and assistant professors, and seventy-one instructors. A high school and an elementary school, which are distinct and separate organizations from the College, serve as model and practice schools for students intending to teach. George Samler Davis, LL.D., is the president. G. S. D.

NORMAL SCHOOL.—An institution for the preparation of candidates for the teaching profession. The English term is borrowed directly from the French *école normale*. In 1794 (Oct. 30) the Convention decided to create in Paris "an *École Normale* where citizens of the Republic already instructed in the useful sciences should be taught to teach." The course was to last five months and the students were to return to their own districts and there open other normal schools. The school was opened on Jan. 20, 1795, and closed on May 15 of that year. Lagrange, Laplace, Berthollet, and Bernard in de Saint-Pierre were on the faculty. *Écoles normales* became the established name for the institu-

NORMAL SCHOOLS, JUNIOR

tions for the training of teachers. The term was transferred to England in the thirties. In 1833 Roebuck (*q.v.*) urged the importance of creating "normal schools" for training masters, and in a Minute of Committee of Council of 1839 the establishment of a national normal school was advocated: "to found a school in which candidates for the poorer classes may acquire the knowledge necessary to the exercise of their future profession, and may be practiced in the most approved methods of religious and moral training and instruction." The scheme fell through, however, owing to the opposition of the National Society and the British and Foreign School Society.

The importance of professional training of teachers had received sporadic attention in the United States from the latter part of the eighteenth century. The numerous academies (*q.v.*) which formed so conspicuous a part of the educational system of the times included in their function the preparation of teachers, so far as they were prepared. In the charter of the very first of these institutes, the "Academy and Charitable School of Philadelphia in Pennsylvania" the training of a number "of the lesser sort" as teachers was specified as one of its functions. With academies the training of teachers was incidental and could hardly be termed professional; at least not until after the adoption in 1834 of the New York system of dividing portions of the state funds among the academies for this specific purpose. When the importance of special professional training began to be recognized, the term teachers' seminaries was applied to the institution which was advocated, though academy for teachers was also used. With the publication in translation of Cousin's (*q.v.*) *Report on the State of Public Education in Prussia* in 1834 and Calvin E. Stowe's (*q.v.*) *Report on Prussian Schools* in 1837, the use of the term Normal School as distinctive becomes quite general, though it is not used in the report nor in the statutes framed by the Massachusetts legislation committee in 1838, which resulted in the first normal school in the United States. The term, however, was applied to the resulting institutions, opened at Lexington (later at West Newton), 1839, at Barre (later at Westfield) and at Bridgewater in 1840. The New York Normal was established in Albany in 1875, the Pennsylvania one at Philadelphia in 1848, the Connecticut one at New Britain in 1849, and the Michigan one at Ypsilanti in 1850. The entire subject is discussed under the caption **TEACHERS, TRAINING OF**.

NORMAL SCHOOL OF THE CONVENTION.—See **FRANCE, EDUCATION IN**; **NORMAL SCHOOLS**.

NORMAL SCHOOLS, JUNIOR.—See **JUNIOR NORMAL SCHOOLS**.

NORTH CAROLINA COLLEGE

NORTH CAROLINA COLLEGE OF AGRICULTURE AND MECHANIC ARTS, RALEIGH, N.C.—Founded in 1889. It is one of the land grant colleges provided for in the Morrill Act of 1862, and is therefore a federal as well as a state institution. The college offers degree courses in agriculture, civil engineering, mechanical engineering, electrical engineering, chemistry, and textile industry. The enrollment has reached 630 students, 240 of whom are in the agricultural courses. It has 587 graduates. The college owns about four hundred acres of land, a mile and a half west of Raleigh. The buildings number nineteen, and, with the farm, aggregate in value \$850,000. E. B. O.

NORTH CAROLINA STATE NORMAL AND INDUSTRIAL COLLEGE, GREENSBORO, N.C.—Was established in 1891 by the State for the higher education of the white women. It is supported by legislative appropriation. The board of directors is appointed by the State Board of Education. Tuition is free to those who agree to teach two years in the state. The usual undergraduate courses are offered leading to the bachelor's degree in arts, science, pedagogy, music, and home economics. Admission is by certificate of an accredited high school or by examination. The Faculty, including instructors, numbers sixty-five; total number of students is 650. Extension work in elementary agriculture, education, and home economics, is conducted by lectures, correspondence, bulletins, and field work. There are fourteen buildings on a campus of 100 acres, valued at \$650,000. The annual state appropriation is \$87,000. J. J. F.

NORTH CAROLINA, STATE OF.—One of the thirteen original states, having ratified the Federal Constitution in 1789 as the twelfth state. It is located in the South Atlantic Division, and has a land area of 48,740 square miles, or about the same size as the state of New York. For administrative purposes the state is divided into ninety-eight counties, and these in turn into cities, towns, and rural school districts, though the township as an intermediate government unit is also used in a number of the counties. In 1910 North Carolina had a total population of 2,206,287, and a density of population of 45.3 persons per square mile.

Educational History.—Educational development in the colony was slow, owing to bad government and the slow growth of population. The first professional teacher, Charles Griffin, opened a school in Pasquotank county about 1705. In 1708 this school was turned over to a representative of the English Society for the Propagation of the Gospel (*q.v.*). In 1712 a school was opened at Sarum, and the Society sent over a number of parish libraries. Little was done under the proprietary form

NORTH CAROLINA, STATE OF

of government, which ended in 1729, or under the earlier period of royal control. In 1736 the colonial Governor urged the establishment of schools in his message, but no action was taken. At that time the colony did not possess either a printing press or a printed edition of its laws, and schools were naturally not regarded as important. In 1745 the first school law was enacted. This merely granted to the town of Edenton the right to build a school-house by means of donations and subscriptions, but there is no evidence that it was ever built. School laws were proposed in 1749 and 1752, but were refused passage. In 1754 George Vaughan, a London merchant, proposed to give to the colony £1000 to propagate the Gospel among the Indians. This was met by a counter-proposal, that if changed to a public school or a seminary of learning, the colony would add £6000 to the bequest. This was done that year, but soon after the fund was spent for defense in the French and Indian War, and the plan came to naught. In 1766 an act incorporating a Society for Promoting and Establishing the Public School in Newbern was passed. This was practically the first law passed in the province for the encouragement of public education. Trustees were to be chosen, their duties specified, and a duty of one penny a gallon on all liquors imported into Neuse River was levied for the next seven years, to provide free education at the school for ten poor children. The teacher was to belong to the Church of England, and to be licensed by the Governor. In 1767 and 1768 similar bills to establish a school in Edenton were passed, but vetoed because the assembly refused to require the teacher to be a member of the Church of England. In 1771 the people accepted this condition, and a school was established. Only English Church schools, either public or private, were allowed in the colony during the period of English control. All schoolmasters were required to be licensed by the Bishop of London, to conform to the Anglican liturgy, and to have received the Sacrament in some Anglican Church within a year, under penalty of three months' imprisonment; a similar penalty and perpetual disbarment from teaching was imposed for attending any other form of worship. This law was enforced in the eastern part of the state, which was largely English, but in the western part, where there were many settlements of Germans, Scotch, Scotch-Irish, and Quakers, many parochial schools were established in connection with their churches. Presbyterians from New York and Pennsylvania, and graduates of Princeton College not only gave an impetus to elementary religious instruction, but also began the founding of the academies which later were such a marked feature of education in the state. Tate's Academy at Wilmington, established about 1760, was the first. Crowfield Academy,

Caldwell Academy, Poplar Tent Academy, Clio's Nursery and Academy of the Sciences, and Queen's College (afterwards Liberty Hall Academy) were established before the Revolution.

In 1776 the state adopted its first constitution, and in this was incorporated a provision, copied from the Pennsylvania constitution, directing that a school or schools should be established by the legislature, "with such salaries to the masters, paid by the public, as may enable them to instruct at low prices;" and that all useful learning should be promoted "in one or more universities." In 1789 the University of North Carolina was chartered, and organized in 1795, but no action was taken toward the establishment of public schools until 1816. Private academies were chartered, however, in numbers. By the close of the eighteenth century, legislative charters had been granted to thirty-two academies; up to 1810 to seventy; by 1815 to 102; and by the close of 1825 to 171. The earlier academy charters were almost all alike. A number of individuals were given corporate powers, and absolute control over the establishment and management of the academy. In the earlier charters it was specified that such schools were not to be considered as the institutions of learning provided for in the constitution. Freedom from taxation and the right to raise money by a lottery were sometimes given. The first school society for the education of females was chartered in 1811. After about 1815, the stock company form of charter appeared, and library societies and benevolent educational societies also began to be chartered.

In 1804, 1806, 1811, 1815, and 1816 the different governors recommended to the legislature that they make some provision for the education of the people, but it was not until 1816 that the legislature took any action. The result was the adoption of a resolution, authorizing the appointment of "three persons to digest a system of public instruction, . . . and to submit the same to the consideration of the next general assembly." This was done, and the plan submitted to the legislature of 1817. It provided for the creation of a state School Fund; a Board of Public Instruction to manage the fund and carry the plan of public instruction into execution; a system of schools, embracing primary schools, academies, and the state university; outlined the course of instruction, the method of instruction, and the form of school government; provided for the free education of all poor children in the primary schools, and for the brightest in the academies and the university; and for an asylum for the education of the deaf and dumb. The expense involved made the plan prohibitive; its friends demanded its adoption entire or not at all; and the result was no action. Nothing further

was done until 1824, when a new commission was appointed to prepare a feasible plan. A bill providing for the education of the poor was the result, but it was not adopted.

In 1825 the beginning of a state school system was finally made, with the creation of the literary fund, and the beginning of an effort to carry out the mandate of the constitution of 1776 was made. It was not until 1839 that an elementary school system was finally provided for. The act of 1825 created a permanent fund, consisting of certain bank and navigation companies' stock held by the state, all liquor licenses and land entry fees, and the swamp lands of the state; created an *ex officio* board, known as "The President and Directors of the Literary Fund," to manage the fund; and decreed that the income should be applied "to the instruction of such children as it may hereafter be deemed expedient by the legislature to instruct in the common principles of reading, writing, and arithmetic." The principal of the fund was about \$50,000 in the beginning. The income was added annually to the principal, and by 1836 it had reached \$242,045. All but \$300,000 of the Surplus Revenue (*qv*) received in 1837 was added to the fund; in 1838 the fund was reported as \$1,732,485; and in 1840 as \$2,241,480. In 1831 an act to raise a fund to establish free schools in Johnston county, and an act prohibiting the teaching of reading or writing to slaves were passed. In 1832 there was some agitation for the establishment of a monitorial system of education for the state. In 1835 the constitution of 1776 was revised, but with no change or addition to the clause relating to education. In 1837 the Literary board was changed to one consisting of the Governor and three appointed by him, and \$208,000 were appropriated from the fund to drain the swamp lands of the state. It was not until 1839 that the first law providing for the organization of schools was passed.

In 1838 the directors of the Literary Fund made a detailed report to the legislature, and submitted a plan for the organization of public schools. In 1839 a law was finally passed, providing for the election of from five to ten persons in each county, by the county courts, to act as superintendents of common schools. They were to divide the counties into school districts, not over six miles square, and to appoint three to six school committeemen for each district. County courts were to levy a school tax of \$20 per district, and the state was to grant \$40 per district from the Literary Fund. A school census was also provided for. A referendum on the law was provided for, and it was not to go into effect in any county until adopted by the voters. In 1839-1840 sixty districts in four counties received grants, and these were the first payments from state funds made by the state.

These marked the beginnings of public common schools in North Carolina.

From 1840 to 1852 has been called the experimental period. In 1840 the law of the preceding year was revised and improved. The board of county superintendents was to elect one of their number as chairman, and this step marks the beginning of the county superintendency. The income of the Literary Fund was now to be apportioned to counties accepting the law, in proportion to the federal census, and then to the districts by the board of superintendents. The census of 1840 shows that there were then in the state two universities, 141 academies and grammar schools, 632 primary and common schools, and 19,483 pupils in attendance at the 775 schools of different kinds. By 1850 there were 2657 schools and institutions, and 104,095 pupils. In 1844 the system as established was somewhat crippled by an increase in the number of school districts, accompanied by a decrease in the taxes. By 1846 the laws of 1839 and 1840 had been finally adopted by all of the counties, though a number still did not levy a local tax. In 1849 the first edition of the school laws was printed and distributed. In the same year the legislature authorized the appointment of county superintendents. In 1852, after some years of effort, a law was secured providing for the appointment of a State Superintendent of Common Schools, to be chosen by the legislature, for two-year terms, at a salary of \$1500. Up to this time the directors of the Literary Fund had exercised all the state supervision there had been. The first appointee, Dr. Calvin H. Wiley, occupied the position until legislated out of office in 1866, and to his efforts the reorganization and development of the system are largely due. The eleven annual reports made by him during his term reveal a constant increase in schools, attendance, and interest in public education. In 1855 the school law was revised and reenacted. By 1858 a four months' average term of school was maintained in the state, and by 1860 there were six colleges for males, thirteen for females, 350 academies and select schools, and 4000 primary schools in the state, with a total enrollment of 177,400. The school system of North Carolina was at this time, perhaps, the best of any of the slaveholding states, and compared favorably with some of the northern and western states.

The Civil War stopped this development. In 1861 the counties were given permission to omit taxes for schools during the War, although most of them did not do so. As late as 1863 fifty counties report 1076 schools as still in existence, and in 1864 an act to grade the common schools was passed. At the outbreak of the War, the Literary Fund amounted to over \$2,000,000, and it is much to the credit of the state that the integrity of this fund was respected throughout. At the close of the

War the bank stocks, in which more than one half of the fund was invested, were worthless, and the other assets were finally sold for a fraction of their former value. The proceeds were invested in North Carolina special tax bonds, but these were later repudiated by the state, and the remainder of the fund was lost. The only asset of value remaining was the swamp lands, and out of these the present fund has been almost entirely built up. In 1873 the fund was only \$23,307; in 1910 it was \$456,471, with some swamp lands still unsold. The loss of the school fund caused the schools to close in 1865, and they were not reopened again until 1870. The University of North Carolina continued open until 1868, was closed during 1868-1869, was opened again during 1869-1870, and then was closed until 1875.

A new state constitution was prepared in 1866, but rejected by the voters. Another was prepared in 1868 and adopted. This provided for a fully organized state school system for all children in the state. A State Superintendent of Public Instruction, elected by the people for four-year terms, superseded the Superintendent of Common Schools, and an *ex officio* State Board of Education superseded the old President and Directors of the Literary Fund. A state school fund was provided for, succeeding to the assets and income of the old Literary Fund. The district school system and a four months' school were ordered, and a compulsory education law sanctioned. Detailed constitutional provision was made for the University of North Carolina, and for the establishment, later, of an agricultural department. Some schools were opened, but they did not prosper. The state was impoverished, the insistence upon equality for the colored children was offensive, and the appointment of a negro as Deputy State Superintendent did not improve matters. In 1876 the people, having passed through the Reconstruction period, adopted another new constitution. The educational provisions of the constitution of 1868 were continued in the new constitution with but few changes. Equality of privilege, but separate schools for the two races, were made mandatory. The Superintendent of Public Works was dropped from the State Board of Education; the detailed provisions for the University of North Carolina were omitted; and the legislature was directed to establish a normal, as well as an agricultural department, at the university.

For some time schools and school expenses increased very slowly. After about 1880, the state began to recover somewhat from the devastation of the War, and educational conditions began to improve, though it was not until about 1900 that the expenditures for school purposes, schoolhouse valuations, attendance at school, and length of term began

to increase at all rapidly. Since 1900 progress has been marked. The most serious drawback to educational development, aside from the comparative poverty of the state, has been the constitutional limit placed on local taxation. This was not removed until 1907. During these early years much valuable assistance was received from the Peabody Fund (*q.v.*), and some assistance is still received from this foundation and from the General Education Board (*q.v.*). In 1876 the first city school system was organized under a special act of the legislature, so as to permit of the levy of a local tax. By 1886 eight such acts had been passed; by 1896, sixteen; and by 1906 seventy-eight. Special taxing districts have also been formed by law in almost all of the counties. In 1876 the first two normal schools, one for each race, were established; and in 1881 two more for each race were created. The number for colored teachers finally rose to seven, but in 1903 these were consolidated into four. In 1881 a new consolidated school law was enacted; the state tax for education was increased to twelve and a half cents; and county superintendents of schools and county teachers' institutes were created. In 1885 County Boards of Education were also created, and in 1909 these were improved by having the terms of members lengthened from two to six years, one, instead of all, going out of office each biennium. In 1889 an Agricultural and Mechanical College for whites and in 1891 a similar institution for colored students were established. A state institution for the deaf and dumb was also created.

In 1899 the first state appropriation of \$100,000, to aid in securing the four months' school required by the constitution, was made by the legislature; in 1901 this was doubled; and in 1909 further increased to \$225,000, and its method of apportionment much improved. In 1901 the rural school library law was enacted, and in 1903 the law extending aid to established libraries was added. In 1903 the policy of using the State School Fund (Literary Fund) as a loan to the districts to build schoolhouses, at 4 per cent interest, one tenth repayable annually, was begun. The Appalachian Training School for white teachers was also established in this year. In 1907 the high school law with state aid of \$45,000 annually (since increased) was enacted; high school courses were to be prescribed by the State Superintendents; high school teachers' certificates were first provided for; the first compulsory education (an optional law) and child labor laws were passed; the education of the deaf and dumb was made mandatory; the East Carolina Teachers' Training School was established; and subcommissions of teachers, to assist the State Textbook Commission in adopting textbooks, were provided for. In the same year the Supreme Court of the state reversed a former decision, and made possible

a county tax for schools, even though the ordinary tax limit had been reached. In 1909 the legislature enacted a county school tax law, permitting a county tax for schools up to five cents, and fifteen cents on the poll, and the legislature of 1911 increased the limits six times. In 1909 teachers' institutes were made mandatory for each county, at least biennially; and in 1911 all teachers were required to attend a summer institute or a summer school at least once in two years. In 1909 county boards of education were authorized to order the enforcement of the compulsory education law at their discretion without waiting for local adoption. In 1911 the "County Farm-Life Schools" law was passed.

Present School System.—At the head of the present school system is an *ex officio* State Board of Education and a State Superintendent of Public Instruction. The State Board consists of the Governor, Lieutenant-Governor, Secretary of State, Treasurer, Auditor, Attorney-General, and the State Superintendent. They have corporate powers, the general government of the schools and the State School Fund, and succeed to all the powers and duties of the President and Directors of the Literary Fund. The Board is also *ex officio* a State Textbook Commission, has control of the colored normal schools, and selects trustees for white normal schools. It makes all loans from the permanent school fund to the county boards for building schoolhouses, as provided for by the law of 1903; may increase the statutory studies for elementary schools; and approves the establishment of high schools in counties. The State Superintendent of Public Instruction is elected by the people for four-year terms. He is *ex officio* a member of the State Board, and also acts as its executive officer. He publishes the school law; signs the orders for all state money paid out; has the general direction of the school system of the state and the enforcement of the school law, and all school officers are to obey his instructions and interpretations; he appoints institute conductors, and determines the time and place of holding the county institutes; prescribes the course of study for the high schools of the state, and inspects state-aided schools; makes rules and regulations; prepares lists of books for the rural school libraries; and approves all schoolhouse plans. He is required to know educational conditions in all parts of the state; to keep in touch with educational progress in other states; and to make a biennial report to the Governor. He acts as Secretary of the State Board of Education and of the State Textbook Commission; as a trustee of the State Library and of the Appalachian Training School; is President of the Board of Trustees (or Directors) of the State Normal and Industrial College, and of the Eastern Carolina Training School; is chairman of the State Board of Examiners;

has supervision and control of the normal department of the Cullowhee High School; and is a member of the Advisory Board on farm life education, which outlines the course of study for the County Farm Life Schools.

For each county there is a county board of education, and a county superintendent of schools. The county boards of three members are elected by the legislature, for six-year terms, one each biennium. Vacancies are filled by the State Board of Education. Members are paid \$2 per day and mileage, and no teacher is eligible for appointment. The county boards have corporate powers as to acquiring, holding, and disposing of school property; have power to make rules and regulations for schools, teachers, pupils, and attendance; determine the time for opening and closing the schools; contract for and direct the building of all new schoolhouses, and may condemn land for the same; may pay one half the cost of the same from the building fund; control all loans from the state fund to the districts for building; estimate the annual county tax needed to maintain a four months' school; may create, abolish, and consolidate school districts, and provide transportation for pupils of either race; have power to enforce the school law in their county; may remove any teacher or school committeeman, for cause; on complaint of the State Superintendent, may remove the county superintendent, or one of its own members; approve the annual report of the county superintendent; publish an itemized account of receipts and expenditures; appoint all school committeemen, except in cities under special charter; appoint a custodian for the district libraries, and control their establishment and aid; may establish and maintain county high schools, with the consent of the State Board of Education; may arrange for free tuition of pupils in existing high schools; have control of the enforcement of the compulsory education law; apportion the county school funds; and may call elections for the establishment of County Farm Life Schools, or for the voting of a county school tax. They elect the County superintendent of schools, who acts as their secretary and executive officer. He is elected for two-year terms, and need not be a resident of the county when elected. He must be "a practical teacher, and have had two years' experience." He must devote his entire time to the work, and his salary is determined by the county board. He must attend the annual state meeting of county superintendents and the district superintendents' association. He advises with the school committees; exercises a general supervision over the schools; examines teachers for county teachers' certificates; is *ex officio* a member of the Board of Trustees for the County Farm Life School, and supervises the work of the school; and makes an annual report to the State Superintendent.

In some counties the township system of control prevails, and in others the district system. For each township or school district in the county the county board of education appoints three persons, for two-year terms, to act as a school committee. They are to care for the property of the township or district, and have immediate control over the same; they take a biennial school census; purchase school supplies, up to \$25 a year, on the order of the county board; they employ all teachers for the schools for a maximum term of two years; and they may contract with a private school in their township or district (if not sectarian or denominational) for the education of the public school pupils. Such a school then becomes a public school. The county treasurer is treasurer of each township or district, and pays out funds on orders from the school committee.

Cities and towns operate under special charters, have their own superintendents, and are not under the control of the county boards of education, except in a general way, although most general school laws apply to such special districts as well. Town and city school committees consist of five to seven members, and are appointed by the boards of aldermen. The town or city constitutes one school district, and the school committee provides such schools for each race as seem equitable and just. Any union of two or more districts, a town, or a city may employ a superintendent of schools, if the county board of education consents. Textbooks, uniform for the state, are adopted by the State Textbook Commission.

School Support. — Until recently the schools have been greatly retarded by lack of sufficient funds. State aid was not granted until 1899, and as yet is small. In 1907 a favorable Supreme Court decision opened the way for the first time for adequate county school taxation. An annual state appropriation of \$125,000 is distributed to the counties on the basis of school census. A further state appropriation of \$100,000, less \$7,500 for aiding rural school libraries, is apportioned to the counties levying a county school tax, and in such a manner as to duplicate sums raised locally, secure a four months' school, and equalize terms. Under the new law of 1909 it is the duty of the county board of education to estimate the amount of money needed each year to maintain a four months' school uniformly throughout the county, and it is the duty of the county authorities to levy the amount estimated, up to a tax of five cents on the \$100 and a poll tax of fifteen cents. Under the 1911 law they may also request a general county election to vote an annual county tax in any amount up to thirty cents and ninety cents poll. All proceeds of estrays, fines, forfeitures, liquor and auctioneer licenses, and three fourths of the general poll tax of \$2 also

go to the county school fund. In apportioning this fund to the districts, the county board may set aside from $7\frac{1}{2}$ per cent to 20 per cent as a Building Fund, and the remainder must be so apportioned to the different townships and districts as to enable all to provide an equal length of term. While the census basis is to be used as a first approximation, it may be ignored entirely if necessary to equalize educational advantages throughout the county. Cities and towns may vote a local school tax up to thirty cents, and ninety cents poll. Special tax districts may also be formed by the county boards of education, without reference to township lines, for the levying of a similar tax. In 1900 there were but 30 such special tax districts; in 1904, 228; and in 1910, 995. In addition any township may vote a special township tax of from ten to thirty cents and from thirty to ninety cents poll for a township high school. In all cases a petition is presented and an election called. If the proposition is carried, then the tax becomes an annual tax, the school committee of the district determining the amount each year, up to the maximum limit voted.

Educational Conditions.—Ten years ago North Carolina was one of the most backward states educationally in the Union, but the last decade has witnessed a wonderful change and improvement. The great increase in local taxation, as well as the beginning of state grants for elementary schools, high schools, and libraries, are marked features of the recent development. Expenditures for education have trebled in ten years, while the school population has increased but 5 per cent. The average term has been increased from 77 to 102 days in the same period, school property greatly improved, about 2500 rural school libraries have been created, high schools developed in nearly every county, some marked progress has been made in the consolidation of rural schools, and a strong sentiment awakened in favor of better education in the state. A State Inspector of Rural Schools has been provided by the Peabody Fund (*q.v.*), the state has provided a supervisor of institutes, reading circles, and normal training; and a state supervisor of agricultural instruction and extension work has been provided by the General Education Board (*q.v.*). Instruction in domestic science is provided for in the colored normal schools from the Slater Fund (*q.v.*). The State Board of Health has coöperated in giving instruction in hygiene and public health. The Committee for the Promotion of Public Education in North Carolina, aided by the Southern Education Board, has carried on a vigorous educational campaign in the state. Aided by the Peabody Fund, the Woman's Association for the Betterment of Public School Houses and Grounds has kept a traveling representative in the field.

One third of the total population is of the negro race, and in a few counties these outnumber the whites. The negroes own very little property, yet the state attempts to provide equality of term and opportunity for the children of the two races. The state maintains schools for Indian children in three counties, although there are but about 1000 of these, and also an Indian Normal School. The state has no foreign population to contend with, less than $\frac{1}{2}$ of 1 per cent being foreign born. In illiteracy the state has in the past ranked rather high, but a determined effort has been made to stamp this out by providing equal educational advantages for all, and by compulsory education. The state is essentially rural and agricultural. About 85 per cent of the total population live in country districts, there are no large cities in the state, and manufacturing has not as yet developed to any large extent.

Secondary Education.—A strong effort to develop high schools has been made within recent years. The high school law of 1907, the requirement of high school teachers' certification, and the inspection and approval of the course of instruction by the State Superintendent have done much good. The first year after the passage of this law 156 high schools were established, and by 1910 the number had reached 170. In addition, one white school in five and one colored school in twenty-five are reported as offering some high school instruction. Any county board of education may establish one or more high schools in a county, and appoint a high school committee of three to manage each school, or may arrange for free tuition of pupils in existing town schools. All such schools must have at least three teachers, one of whom must be engaged wholly in high school work. Many of these schools are in part grammar schools, offering only the first two years of high school instruction. Schools, outside of towns of 1200 or more inhabitants, may receive state aid under rules and regulations adopted by the State Board of Education, and any school may be aided for tuition pupils received, the state paying one half of the expense up to \$500 per school. All high schools must provide a five-months' term. Secondary education for the colored race is provided in the state normal schools, the State Normal and Industrial School at Burgah, the State Agricultural and Mechanical College at Greensboro; and in some twenty other institutions of secondary rank, mostly denominational in control, a number of which are industrial in type.

The new County Farm Life Schools (1911) are also an interesting secondary school development. One is to be established eventually in each county, at the rate of ten a year, and each is to receive \$2500 aid annually. Each school must have twenty-five acres,

dormitory, barn, dairy, and school building; offer instruction in practical farm life and home-making to both sexes; and short courses and extension courses to farmers and their wives. An ordinary high school department is also to be maintained, and all teachers must hold high school certificates. Counties are to vote to establish such schools, and issue bonds to equip them. To govern these schools, the county board of education is to appoint one person from each township in the county to act as a board of trustees, with the county superintendent as an *ex officio* member.

Teachers and Training.—Of the 11,216 teachers employed in 1910, one fourth were in schools for the colored race. Of the white teachers 31 per cent had had normal training, and 20 per cent held college diplomas, while of the colored teachers 46 per cent had had normal training, and 15 per cent held college diplomas. For the training of future teachers the state maintains three normal schools for white students, one for Indian students, and three for colored students. All teachers' certificates must be obtained on examination, as the law distinctly provides that no diploma of any college or normal school shall give the holder the right to teach in the state without submitting to an examination.

Higher and Special Institutions.—The University of North Carolina at Chapel Hill, founded in 1789; the North Carolina College of Agriculture and Mechanical Arts for white students at West Raleigh, founded in 1889; and the Agricultural and Mechanical College for the Colored Race at Greensboro, founded in 1894, stand as the culmination of the public school system of the state. In addition to the above, eight collegiate institutions for women, four for men, and seven for both sexes, nine of which were founded before the Civil War, also assist in the work of higher education in the state. Some half dozen additional institutions, mostly denominational, offer collegiate instruction for the colored race, the most important of which is Shaw University (*q.v.*) at Raleigh. E. P. C.

NORTH CAROLINA, UNIVERSITY OF, CHAPEL HILL, N. C.

—The oldest of the state universities, in the actual teaching sense, chartered in 1789. The first session began in 1795. Around the University sprang up the town of Chapel Hill. The first president of the University was Joseph Caldwell, a graduate of Princeton, and in the beginning it was patterned after that institution. While established and controlled by the state, no direct appropriation was made either for buildings, equipment, or support during the first ninety years of its existence. It was dependent upon donations, certain escheated property, and the fees of the students. Still it flourished and was progressive and vigorous under President Caldwell. The first state geological survey was organized in 1823 by members of its faculty, and the first college observatory was built there in 1827.

On the death of Caldwell in 1835 David L. Swain became president. Under him various buildings were added and an endowment of several hundred thousand dollars accumulated. The University expanded until by the opening of the Civil War it was attended by 430 students, about half of whom came from outside the state, representing every Southern state. During this first half century of service it had furnished one president of the United States and one vice president, many senators, representatives, members of the cabinet, and other national officials, besides some 60 per cent of all the leading officials, civil and judicial, in its own state.

The sacrifice and the loss of this institution in the Civil War is perhaps unparalleled. Fourteen members of the faculty volunteered; seven gave up their lives. About 45 per cent of the living alumni entered the service, and nearly 30 per cent of these were killed or died in the service. More than twenty generals were furnished to the Confederate armies and one to the Union. About half of the regiments furnished by North Carolina were commanded by the University's alumni. The close of the war saw the University practically beggared. Under order of the court all of its property except the immediate buildings and such woodland as was necessary for furnishing fuel was sold to meet its bonded and other indebtedness. In 1869 President Swain died. The University dragged through two or three years of the Reconstruction Period as a sort of high school and was then abandoned, losing most of such apparatus as was left, its buildings lying open and uncared for. Only its books and collection of portraits were preserved.

NORTH CENTRAL ASSOCIATION

Reopened in 1875, friends and alumni contributed for its repair. The state paid for its support the interest on the Land Scrip Fund amounting to \$7500, the state treasury having been looted of the original fund. This payment was discontinued in 1887 when the Agricultural and Mechanical College was established at Raleigh. In 1876 Kemp P. Battle was elected president and continued in office until 1891, the University thus almost rounding out its first century under three presidents.

The struggle with poverty and against strong denominational antagonism was severe; the rebuilding was slow and arduous. All hope of regaining the large patronage from other Southern states was gone. In 1881 the state began to make appropriations for maintenance and a little later for repairs and ordinary equipment, but the first appropriation for a building was made in 1905 — just 110 years after the opening of the University. It has a campus of fifty acres, some twenty odd buildings, a library of 65,000 volumes, and all together property approaching \$1,500,000 in value. Its total income amounts to \$175,000.

The University has grown into an institution with a faculty numbering nearly 100 and more than 800 students. It comprises a college of liberal arts and a college of applied science and well-developed schools of graduate studies, law, medicine, and pharmacy. The entrance requirements are fourteen units. F. P. V.

NORTH CENTRAL ASSOCIATION OF COLLEGES AND SECONDARY SCHOOLS. — See EXAMINATION AND CERTIFICATION BOARDS.

NORTH DAKOTA, STATE OF. — Organized as a Territory by Congress in 1861, and at that time embracing 350,000 square miles. In 1864 Montana Territory, and in 1868 Wyoming territory were set off, and in 1889 the Territory was further divided, and admitted as two states of almost equal size, — North Dakota as the thirty-ninth state, and South Dakota as the fortieth. North Dakota is located in the western part of the North Central Division of states, and has a land area of 70,183 square miles. It is about the same size as the six New England states and New Jersey combined. For administrative purposes the state is divided into forty-six counties, and these in turn into townships, though five of the older counties still retain in part the district form of school organization. In 1910 North Dakota had a total population of 577,056, and a density of population of 8.2 persons per square mile.

Educational History. — At the first Legislative Assembly in 1862 "An Act for the Regulation and Support of Common Schools" was passed. This provided for the appointment of county superintendents, the division of counties into school districts, the election

NORTH DAKOTA, STATE OF

of boards of three trustees for each district, an annual district tax, a three months' term of school in each district, the examination and certification of teachers, and for graded and union schools. It is doubtful whether many school officers were appointed or any schools were opened under this law. The Territory had but few people, and the Indian massacres and war of 1862 left Yankton (S. Dak.) the only settlement. In 1864 an *ex officio* Territorial Board of Education was created, which was to appoint a Territorial Superintendent of Public Instruction. In the first report of this Board in 1864, no public schools (though a few private schools) are mentioned in the Territory, and but few counties had appointed county superintendents. In 1865 there were but four legally organized school districts in the Territory, and a few private schools, with a total combined school enrollment of 382 pupils, and a school census of 621. In 1866 the *ex officio* Territorial Board was replaced by one of three specified persons, who, however, failed to qualify. In 1868, and again in 1869 and 1871, the school law was revised and re-enacted, though without substantial changes. In 1867 the office of Territorial Superintendent was made elective, and for two-year terms, and a county school tax of two mills and \$1 poll were added to the previously authorized district taxation. In 1867 teachers' institutes of from four to ten day's duration were authorized; in 1873 optional county teachers' institutes were permitted; and in 1875 the territorial teachers' institutes were restored. In 1871 a Deputy Territorial Superintendent for the northern part of the territory was provided for by the new law. In 1873 the 100 schools reporting had an attendance of 2006 children, out of a total school population of 5312 in the Territory. In 1875 the school law was again revised, the old provisions for union graded schools dropped out, and a list of textbooks adopted for the schools by name and by general law. In 1877 the Territorial Superintendent was changed from elective to appointment by the Governor and Council, as had originally been the case.

Up to about 1879 the growth in population in the territory had been slow, but during the next five years the school population almost trebled, and educational development was correspondingly rapid. After 1880 the idea of separate statehood for the two parts of the Territory seems to have taken root, and school statistics are reported separately after 1883, for North and for South Dakota. In 1879 women were permitted to vote at school elections, and in 1881 they were made eligible for the office of county superintendent. Bonds for schoolhouses up to \$1500 were first authorized in 1881. In 1881, also, two Territorial Normal Schools were created; in 1882 the University of Dakota at Vermilion (now the University of South Dakota), whose charter

dated back to 1862, was opened for instruction; in 1883 the University of North Dakota at Grand Forks, and the Territorial Agricultural College at Brookings (now the S. Dakota College of Agric. and Mech. Arts), were chartered. In 1885 a State School of Mines was established at Rapid City, and this is now the South Dakota School of Mines.

The school law was completely revised again in 1883, and made into almost a new law. School districts were abolished, and the township form of school organization substituted in all except eighteen of the older counties, and in these exceptions the Boards of County Commissioners were authorized to put the law in force, if they saw fit. Three of the eighteen counties adopted the township form, so that in 1884 there were sixty-five counties under the township form of organization, and fifteen under the district. The act also increased the salaries of county superintendents from \$600 to \$1500; made the beginning of the appropriations for holding institutes by making an annual grant of \$600; provided for county institute funds, to be derived from fees for examinations for teachers' certificates; and provided for the compulsory education of all children, ten to fourteen years of age, for at least twelve weeks each year. Another new school law was enacted in 1887. A Territorial Board of Education of three members was created and given important supervisory authority; normal teachers' institutes were provided for, with state-appointed institute conductors; a state course of study was to be outlined by the Territorial Board of Education; and the Territorial Superintendent was authorized to designate private institutions and to grant aid to them for the training of teachers for the territory.

In 1889 Congress passed an Enabling Act for the formation of a constitution and for the admission of Dakota Territory as two states. (For the subsequent educational history of South Dakota, see special article on that state.) North Dakota framed and adopted a state constitution, and was admitted as a state in the same year. At the time of the admission as a state, the North Dakota public school system consisted of 35 graded and 1366 ungraded schools, with high schools in the cities and in some of the villages. There were also a state university and one state normal school in operation.

The Enabling Act made large grants of land to the new state for various educational purposes, and demanded that the state should guarantee the safety of the grants, and provide for the establishment and maintenance of a system of public schools, open to all children, and free from denominational or sectarian control. The new state constitution guaranteed the safety and proper application of all grants made, and made mandatory the establishment of a system of free public schools,

"extending through all grades up to and including the normal and collegiate courses." The state university at Grand Forks and the normal school at Valley City were perpetuated as state institutions, and the following new state educational institutions were created and located by constitutional provision: a state school of mines, to be located in connection with the state university at Grand Forks; an agricultural college at Fargo; a second state normal school at Mayville; a school of forestry, in one of four specified counties; a state scientific school at Wahpeton; an industrial school and school for manual training at Ellendale; a reform school at Mandan; a school for the deaf and dumb at Devil's Lake; an asylum for the blind in Pembina county; and a department for the training of the feeble-minded, in connection with the state insane asylum. The constitution further provided that "no other state institutions of a character similar to any one of those created by this article shall be established or maintained without a revision of this constitution." All lands granted (See NATIONAL GOVERNMENT AND EDUCATION) were carefully safeguarded as to sale and sale price; the different funds were declared inviolate, detailed provisions were made for the safeguarding of the lands and funds, and the legislature was forbidden to divert any fund, even temporarily; the interest on the permanent school fund was made distributable on school census alone; a State Board of University and School Lands Commissioners, consisting of the State Superintendent of Public Instruction, the Attorney-General, the Secretary of State, and the State Auditor, was created to control the appraisement, sale, and rental of the school lands, and the investment of the proceeds; a State Superintendent of Public Instruction, and County Superintendents of Schools, to be elected by the people, for two-year terms, were made constitutional officers; women were made eligible to vote for any school officer and to hold any school office; sectarian aid was prohibited; and legislation relating to the prevention of illiteracy and the "securing of a reasonable degree of uniformity in course of study, and to promote industrial, scientific, and agricultural improvement," was permitted. The constitution, in its educational provisions, is one of the most elaborate, specific, and mandatory of any framed by the states.

The state legislature of 1890 put the constitutional provisions into operation by the enactment of a new school law, which outlined a good state system of education. A State Board of Education not having been provided for in the constitution, the State Superintendent succeeded to the powers and duties possessed by the old board. He was also charged with the preparation of all examination questions for teachers' certificates in the state, state professional certificates were provided for,

and the organization and management of the State Teachers' Reading Circle was placed under his direction. The new law, dealing with the question of the school unit and compelled to provide for a uniform system, created the district as the unit, but provided that district lines should conform to township lines wherever possible. This permitted conditions to remain as they were, thirty-three counties in the new state using the township as the district, and five counties having the school district form of organization. In 1911 new legislation permitted the rearrangement of district lines in these five counties, with a view to a partial abolition of the district unit.

The first few years of statehood were a trying period, and little new legislation was enacted, although steady educational progress was made. In 1895 a health and decency law, a law permitting any city, town, or school district to provide free textbooks, and a law creating a State High School Board, consisting of the Governor, Superintendent of Public Instruction, and the President of the University, to inspect and classify the high schools, were enacted. Within two years one third of the schools of the state had voted to provide free textbooks and supplies. A state high school course of study was issued in 1895, and a state elementary course in 1897. In 1898 the State Superintendent began to send out traveling school libraries, and in 1899 the plan was established and provided for by law. In 1907 a State Public Library Commission was provided for. In 1905 the teachers' examination law was revised, third-grade county certificates were abolished, and a minimum teachers' wage law was enacted. In 1907 counties were permitted to organize a three to four weeks' summer teachers' training school, in place of the required county teachers' institute, and by 1900 twenty-four counties had adopted this plan. State aid to accredited high schools was first voted in 1899; the state two-mill tax was changed to a two-mill county tax; the consolidation of schools was authorized; the provision of free textbooks and supplies, on a two thirds petition, was made mandatory on school corporations; and increased aid was extended to the county teachers' training schools. A State School Law Commission was created in 1909 to revise and recodify the school laws of the state, and a revised school code, detailed below, was enacted by the legislature of 1911. The legislature of 1911 also enacted a number of important new school laws. The State High School Board was reconstructed, and a State Agricultural and Training School Board was created. Appropriations were made for a State Inspector of Rural and Graded Schools, and a State High School Inspector. State graded and state rural schools, of two classes each, and state consolidated schools, were defined; the requirements and course of instruction for

state approval named; and definite state grants to each provided for on inspection and approval. The grants to the regular high schools were increased, and their inspection and approval also provided for. The introduction of agriculture, manual training, and domestic science into the regular high school courses, and the affiliation of rural schools with such a central high school, were also provided for, and state aid for them voted. A State Educational Commission was also created, to report in 1912.

Present School System — At the head of the present school system of the state is a State Superintendent of Public Instruction, elected by the people. The election is for two-year terms; women are eligible for the office, and the person elected must hold the highest grade of state professional certificate. He appoints his deputies, who must possess similar qualifications, and his clerks and office force. The work which in a number of states is performed either by a State Superintendent or a State Board of Education, or by the two working together, is here split up among the State Boards of Land Commissioners, Library Board, Board of Examiners, High School Board, Normal School Board, Agricultural and Training School Board, and the State Superintendent. Each of these boards has special parts of the school system to supervise. The State Superintendent is *ex officio* a member of each of these Boards. To the State Superintendent is given the general supervision of the school system of the state. He advises with the county superintendents, decides disputed questions under the school law, holds conferences with school officers, prepares and furnishes all blanks and forms; apportions the State Tuition Fund to the counties, edits the school laws, and makes a detailed biennial report to the Governor. He also issues plans for one- and two-room schoolhouses, approves all school-house plans, prepares and prescribes the course of study for the common schools of the state, and prescribes rules and regulations for teachers' institutes, outlines the course of instruction for them, and appoints all institute conductors. He appoints a State Inspector of Rural and Graded Schools to act for him in their examination and approval, and the State High School Board appoints another deputy to act as a State Inspector of High Schools.

For each county a county superintendent of schools is elected by the people for two-year terms. He, or she, must be a college or normal school graduate, or hold a state professional certificate, and must have had at least two years' experience as a teacher. There are no county boards of education in the state. The county superintendent has general supervision of the schools of his county, and must visit each school at least once each year, and advise with teachers and school officers. Once each year he holds a conven-

tion of school officers; may hold monthly meetings with his teachers; and holds an annual teachers' institute, or a teachers' training institute of three to four weeks' duration. He keeps a corrected map of the school districts of his county; apportions state and county funds to the districts; appoints school directors to fill vacancies; decides school controversies, though appeal to the State Superintendent is allowed; and makes an annual report to the State Superintendent. With the County Superintendent of Health he inspects schoolhouses, may order needed sanitary changes, and approves minor alterations. He also acts as an agent of the State Board of Examiners in the conduct of examinations for teachers' certificates; approves petitions for organizing state graded schools, rural schools, and township high schools; and acts, *ex officio*, as a member of the board of trustees, if a county agricultural and training school is established in his county.

The school unit below the county is the township, although in five counties the district system is still used extensively. The 1911 legislation was intended to make these counties in part conform to the plan followed elsewhere in the state. There are in the state, then, school districts, in the ordinary sense of the term, township districts, and certain segregated districts (towns or cities) known as city districts, special districts, or independent districts. These latter segregated city and town districts are under boards of education. For all other school districts a board of three school directors is elected, one each year, for three-year terms. The people of each district also elect a treasurer, for two-year terms, and the board appoints a clerk, not one of their number, who holds office at the pleasure of the board. There must be four regular meetings of each board each year, and in the cities twelve meetings. Each board of school directors has general charge and management of the schools under their charge, the care of the school property, the making of repairs, and the supplying of necessary equipment. They employ all teachers for the schools; may admit non-resident pupils; may add branches of instruction, with the approval of the county superintendent; may call an election to vote money for buildings or to buy sites, up to five acres in extent; and may levy district school taxes up to thirty mills. They must make such repairs and alterations in buildings as are ordered by the county board for sanitary inspection (Co. Supt. of Schools, and Co. Health Supt.), and can only purchase such books for the school library as have been approved by the State Superintendent. They must organize schools within the district (township) wherever there are nine children without school facilities. They determine the time and length of the school term, which must be equal for all schools

in the district, and not less than seven months in any school. They may, and on petition of one third of the residents must, call an election to vote on the question of consolidating the schools, and they may provide stables at the consolidating center. If the district contains sixty children of school age, the board may, and on petition of ten residents must, call an election to decide the question of providing high school facilities for the district. An annual school census must be taken by the clerk, and he must also make a detailed annual report to the county superintendent. Each board must see that all records, reports, and instruction are in the English language.

Cities and incorporated towns may organize as independent districts, and segregate themselves from the township district. A board of education of five is then elected, in place of the three school directors. City districts, formerly organized under special laws, may reorganize as independent school districts, under boards of education with a membership based largely on ward representation. For all such districts the general school laws apply, and the boards of education have the same powers and duties as boards of school directors. In addition, they may establish graded schools, high schools, and such other schools as may be desired; must maintain a term of from seven to ten months; may purchase, sell, and repair schoolhouses; may employ a district school superintendent, and may levy local school taxes, up to thirty mills.

School Support. — On the admission of the state in 1889, the state received the sixteenth and the thirty-sixth sections in each township for schools, a few Indian reservations excepted, and has since been granted the sections in some of these. The total grant to the permanent school fund of the state was approximately two and a half millions of acres, on which a minimum sale price of \$10 an acre was placed. About two fifths of this has since been sold, and at an average price of about \$15 an acre, while recent sales have been for much larger figures. The 5 per cent of land sales grant was also given to the permanent school fund, and this, up to 1910, had produced \$433,905. In all a total permanent school fund of about \$16,000,000 has so far been produced. The land remaining is conservatively estimated as worth \$13,000,000 more, and will probably bring \$25,000,000. In all a fund of \$40,000,000 for common schools seems probable from the proceeds of the enabling act grants for common schools alone. In addition, 500,000 acres, to be selected by the state, were granted for the higher, reformatory, charitable, and public institutions in the state, as follows: state university, 40,000 acres; school of mines, 40,000 acres; agricultural college, 40,000 acres; state normal schools, 80,000 acres; reform school, 40,000 acres; deaf and dumb asylum,

40,000 acres; public buildings, 50,000 acres; and for other educational or charitable purposes, 170,000 acres. The minimum sale price on all of these lands was placed at \$10 an acre, and they should bring two or three times this amount. The income from each grant is to be used for the support of the institution for which it was granted.

The income from the permanent state school fund, together with all state fines, is apportioned quarterly to the counties, and by the counties to the districts, on the sole basis of the school census, six to twenty-one years of age. In addition, each county must levy a two-mill county school and a county poll tax, the proceeds of which are distributed to the districts on the same basis. Counties establishing a county agricultural and training school may levy, as needed, for its maintenance. In addition, any school district or school corporation may levy a district tax in any amount up to thirty mills, for further maintenance and equipment. Moreover, the state makes special appropriations for aid to high schools; to state graded and state rural schools; and for instruction in agriculture, domestic economy, and manual training in regular high schools; levies a state tax of one fifth of a mill for county agricultural and training schools; and a state tax of one mill, to be divided among the different state higher institutions.

Educational Conditions. — The state is essentially a rural and an agricultural state, 89 per cent of the people living in rural districts. There are no cities as large as 15,000 population in the state. The population is almost entirely white. There are a few Chinese and Indians, but practically no negroes in the state. About one third of the total population is foreign born, Norwegians, English-Canadians, Russians, Germans, and Swedes, in the order named, being the predominant foreign peoples and constituting about 75 per cent of the foreign born. These have settled in the rural districts and taken up farming. The large educational funds, the liberal taxation, and the large per capita wealth of the people make the maintenance of a good system of education easier than is the case in many other states, and good laws tend to secure these results. Good schools are maintained generally throughout the state, and the sentiment of the people is strongly in favor of good schools. Expenditures for education have multiplied four times in the past eleven years, though the school population has only doubled. School libraries are found in all districts, and \$25 per year may be spent from the public funds for books. Free textbooks are furnished in about two thirds of the schools of the state. Any school commission or board may employ a medical inspector, and require the examination of its school children. The teaching of agriculture, domestic science,

and manual training has recently been taken up with much enthusiasm, and the teaching of agriculture in central schools, to which rural schools may be affiliated, has recently been provided for. Standards for state graded and state rural schools have been formulated, and a state inspector of rural and graded schools appointed. The state has a good child labor law, and a reasonably satisfactory compulsory education law.

Secondary Education — High Schools are being developed very rapidly in the state, especially within the past five years. By 1911 the number of approved high schools in the state had reached ninety-five, and the total number was much larger. A State High School Board, consisting of the State Superintendent, the Presidents of the State University and of the Agricultural College, two city superintendents of schools, and one citizen, the last three appointed by the Governor, exercise the functions of a State Board of Education for high schools. They appoint a State High School Inspector, who acts as their executive officer, and approves high schools for state aid. Courses of two, three, and four years may be approved. A State Agricultural and Training School Board, consisting of the State Superintendent, President of the Agricultural College, and three practical farmers appointed by the Governor, act as a State Board of Control for, and determine the qualifications of teachers and principals in, the new county agricultural and training schools authorized by the law of 1911. These schools must be provided with a good equipment, and must offer agricultural instruction correlating with that given in the Agricultural College. State aid, up to one half, and a maximum of \$3000 a year, will be granted to such schools. State aid was also provided, to begin in 1912, for regular high schools which add instruction in agriculture, manual training, and domestic science. The State School of Science at Wahpeton; the State School of Forestry at Bottineau; and the State Industrial and Manual Training School at Ellendale are state schools of secondary grade. The encouragement given to communities to form graded schools, and to gradually develop these into two-year high schools; the provision for the gradual evolution of these into three- and four-year high schools; and the strong emphasis placed on instruction in agriculture and domestic economy are strong points in the North Dakota plan for secondary instruction.

Teachers and Training. — A State Board of Examiners, consisting of the State Superintendent as secretary, and four teachers or superintendents appointed by the Governor as additional members, prepares all questions for the examination of teachers, oversees the grading of the answer papers, and grants all teachers' certificates in the state, with the one exception of teachers and principals in the

county agricultural and training schools. This board also serves, *ex officio*, as a State Teachers' Reading Circle Board, and controls both the teachers' and the pupils' reading circles for the state. These have both been in existence for a number of years, and have rendered valuable service. Four grades of teachers' certificates are issued, and form a graded series, each requiring increasing knowledge and experience and having increasing validity; the highest is issued only to college graduates. Special certificates may also be issued in special subjects. Graduates of the University of North Dakota, of the Dakota State Normal Schools, and of other colleges and normal schools within the state offering equivalent instruction may be certificated without examination and on similar terms. For the training of future teachers the state maintains two State Normal Schools at Mayville and Valley City, and graduates of high schools which offer a four-year course, with certain review and professional subjects in the last year, may also receive a teachers' certificate on graduation. A State Normal School Board looks after the normal schools of the state. So far as it applies, work in summer sessions may also be accepted in lieu of examination subjects.

County superintendents may, if they desire, hold teachers' meetings one Saturday each month, which teachers outside of cities and high schools must attend. Superintendents may also hold an annual teachers' institute, or instead may organize a county teachers' training school, of from three to four weeks' duration. State aid of \$100 a year is given each county for teachers' institutes, and, if a county training school is organized, the county must appropriate a sum equal to twice the number of teachers who have taught for four months in the county the preceding year. A portion of all teachers' examination fees also goes to the teachers' institute fund. Teachers are paid for one week for attendance. A state minimum wage law requires a minimum wage of \$35 a month. The average wage for 1910 was \$51.80.

Higher and Special Institutions. — The University of North Dakota and the State School of Mines at Grand Forks, and the State Agricultural College at Fargo, stand as the culmination of the public school system of the state. Fargo College (Cong.) at Fargo; Wesley College (M.E.) at Grand Forks; Grand Forks College (Luth.) at Grand Forks; and the Presbyterian College at Jamestown assist in the work of collegiate education in the state.

In addition to the above institutions, the state also maintains the State School for the Deaf and Dumb at Devils Lake; the state secondary schools, mentioned above; and the State School for the Blind at Bathgate.

NORTH DAKOTA, UNIVERSITY OF, GRAND FORKS, N.D.

— Established by act of the Territorial Assembly Feb. 23, 1883, and opened its doors in September, 1884. In 1911 there were thirteen buildings, representing in their construction and equipment an expenditure of \$700,000. The student body numbers 972; of these 495 are in the colleges, 348 in the summer session, and 129 in the Model High School. The teaching staff consists of 105 members, thirty-seven of whom are of professional grade. The university maintains six colleges: Liberal Arts, Teachers, Mining Engineering, Mechanical and Electrical Engineering, Law, and Medicine; a mining substation at Hebron, N.D., and a biological station at Devils Lake, N.D. The State Public Health Laboratory and Geological Survey are under the authority of the Board of Trustees. The general and departmental libraries contain 45,000 volumes.

The university at the time of its establishment received 126,000 acres of land which, when finally sold, will give an endowment of \$2,000,000. The assets of the university in 1911 amount to \$2,400,000; the annual income is made up of payments from contracts and interest on land sales, the proceeds of the 1½ mill tax, special appropriations for maintenance, and payments of fees and rents. The income in the year 1911-1912 was \$373,000, of which \$32,600 was for buildings, and \$41,000 for operation of the University Commons, leaving for the conduct of the university and its stations \$229,400.

The principle of affiliation of church colleges with the state university was first inaugurated at the University of North Dakota in 1904, resulting in the maintenance of Wesley College, a Methodist school in affiliation with the university.

The university has had the following presidents: Dr. William M. Blackburn, 1884; Professor Henry Montgomery, acting president, 1885-1887; Dr. Homer B. Sprague, 1887-1891; Dr. Webster Merrifield, 1891-1909; Dr. Frank L. McVey, 1909-. F. L. M.

NORTHEND, CHARLES (1814-1895).

— Educational writer; was educated at Dummer Academy and Amherst College. He was principal of the first grammar school at Danvers, Mass. (1836), and was afterwards superintendent of schools at Danvers and at New Britain, Conn. He was for many years

NORTHFIELD SCHOOLS

secretary of the American Institute of Instruction, and was active in other educational associations. His publications, include: *Teacher and Parent* and *The Teachers' Assistant*. These books passed through many editions, and for more than thirty years they ranked as the most popular educational books. He was also the author of *Letters to Parents*, *Exercises in Dictation*, and numerous articles in educational journals. W. S. M.

NORTHFIELD SCHOOLS. — These include Northfield Seminary for young ladies, at East Northfield, Mass., founded in 1879, and Mount Hermon Boys' School, four and one half miles distant, founded in 1881. Both schools are of secondary grade and prepare for college. They were established by the late D. L. Moody, to meet the needs of young men and young women of limited means who were ambitious to acquire the benefits of a thorough Christian education. In addition to this characteristic, two additional features are prominent: (1) The Bible is emphasized in every course of study, and each student is required to take a minimum of two recitations a week in this subject, under systematic instruction. (2) Each student is required to discharge some assigned duty each day in the dormitories, in dining hall and kitchen, or farm. The grounds and buildings of the seminary represent an investment of \$910,174, and the school has an endowment of \$575,188. Mount Hermon Boys' School has invested in grounds and equipment \$1,007,767, with a further endowment of \$627,823.

NORTHROP, BIRDSEY GRANT (1817-1898). — State Superintendent of Schools; was graduated from Yale College in 1841 and from the Yale Theological School in 1845. He taught in the public schools of Connecticut; was agent of the State Board of Education of Massachusetts (1857-1867), agent of the State Board of Education of Connecticut (1867-1873), and Secretary of the State Board of Education (State Superintendent of Schools) of Connecticut (1873-1883). His publications include: *Education Abroad*, *Forestry in Europe*, and *Lessons from European Schools*, and numerous reports on education. W. S. M.

NORTHWEST TERRITORIES, EDUCATION IN — See CANADA, EDUCATION IN.

NORTHWESTERN COLLEGE, FERGUS FALLS, MINN. — A Lutheran denominational institution founded in 1900. The college grounds include eight acres located about half a mile from the center of the city of Fergus Falls. The institution comprises the following six departments: collegiate, normal, preparatory, commerce, music, art. The course of religious instruction is obligatory upon every regular student. There are (1912)

NORTHWESTERN UNIVERSITY

nine instructors. The student body numbers 119. E. J.

NORTHWESTERN COLLEGE, NAPERVILLE, ILL. — A coeducational institution established at Plainfield in 1862 by the Evangelical Conferences of Illinois, Iowa, Indiana, and Wisconsin as the Plainfield College, the present name being adopted in 1864. The college was moved to Naperville in 1870. The following departments are maintained: academy, college of liberal arts, German, commerce, music, art, physical culture. The entrance requirements to the college are fifteen units of high school work. The degrees of A. B., B. S., and B. L. are conferred. The faculty consists of twenty-five members, and the student enrollment in 1911-1912 was 396.

NORTHWESTERN COLLEGE, WATERTOWN, WIS. — An institution founded in 1865 by the Evangelical Lutheran Synod of Wisconsin and comprising preparatory, collegiate, and business departments. The entrance requirements to the college are equivalent to the work of the preparatory department. The college course leads to the degree of A. B. There is a faculty of twelve members, and the enrollment of students in 1911-1912 was 204.

NORTHWESTERN UNIVERSITY, EVANSTON, ILL. — A coeducational institution, founded "in the interests of Christian learning," and chartered on Jan. 28, 1851. The charter provides that a majority of the board shall be members of the Methodist Episcopal Church, but no religious tests are required of students. The trustees chose as the first president Clark Titus Hinman. The university purchased 397 acres of land twelve miles to the north of the center of Chicago on the shores of Lake Michigan. Here the university was established and opened for instruction in 1855. The place was named Evanston in honor of Dr. John Evans, president of the corporation. The College of Liberal Arts was the only department of the institution until 1869, when the Chicago Medical College became a department of Northwestern University. The Law School, founded in 1859, became a department under sole control of the university in 1891. The College of Engineering was established in 1907, although for many years the university had offered courses in engineering in the College of Liberal Arts. The School of Pharmacy was incorporated in 1886 and became a department of the university the same year. The Dental School was organized in 1887 and was made a department of the university three years later. In 1895 the School of Music was established; the School of Commerce in 1908. A preparatory department was established at Evanston in 1859. On the campus, also, is Garrett Biblical Institute in close affiliation with the university.

The total enrollment of the university, 1911-

1912, including the enrollment in the affiliated schools, was 4344. The total enrollment in 1855-1856, fifty-five years previous, was ten. The growth of the university has kept pace with the development of Chicago, the city of its birth. Only one of the institutions of the Middle West that existed in 1850 has now a larger enrollment. The increase in material equipment is not less marked. In the first year the trustees collected on "the scholarship plan" \$90,000, which represented practically their entire assets. Sixty years later the assets amount to about \$9,000,000.

Expenditures for 1910-1911 were \$740,297. The assets of all kinds for 1911 amount to \$9,098,821. The value of buildings and grounds used for educational purposes, including libraries, museums, and sundry equipment, was \$3,376,130, and trust funds, in addition to educational property located in the center of Chicago, was \$4,555,766. The cash gifts for the year amounted to \$288,175.

In Evanston are located the College of Liberal Arts, the School of Music, the College of Engineering, Garrett Biblical Institute, the School of Oratory, and Evanston Academy. On the south side of Chicago is the Medical School, and in Northwestern University Building, situated in the heart of Chicago, are the Law School, the School of Pharmacy, the Dental School, and the School of Commerce. In the Northwestern University Building is also the Gary Library of Law, one of the largest law libraries in existence. Northwestern University Settlement is situated in a congested district on the northwest side of Chicago.

J. C. B.

NORTON, CHARLES ELIOT (1829-1908).

— Professor of the history of art at Harvard University and man of letters. After graduating at Harvard in 1846, he joined an East India counting house in Boston; he was sent, in 1849, to India and returned by way of Europe in 1851. In the following year he published anonymously *Five Christmas Hymns* and in 1854 a *Book of Hymns for Young Persons*. He still intended at the time to enter the ministry. In 1855-1857 and in 1868-1873 he was in Europe and made the acquaintance of the leading men of letters in England, including Carlyle, Ruskin, and Fitzgerald. He was a frequent contributor to the *Atlantic Monthly* almost from its establishment, and with Lowell he took charge of the *North American Review* from 1864 to 1868. In 1860 he wrote *Notes of Travel and Study in Italy*. He was appointed professor of the history of art in 1875 and held this office until he became professor emeritus in 1898. He organized exhibitions of drawings of Turner (1874) and Ruskin (1879). His reputation rests mainly on his work as an inspiring teacher and on his Dante studies and translations. He translated the *Vita Nuova* (1860 and 1867), and

the *Divina Commedia* (1891-1892). In 1881 he founded the Dante Society. His other works include: *Historical Study of Church Building in the Middle Ages: Venice, Siena, Florence* (1880); *Letters of Carlyle and Emerson* (1883); *Carlyle's Letters and Reminiscences* (1886-1888); *Letters of Lowell* (1894); and as literary executor for Ruskin he wrote introductions to the American edition of his works.

NORTON, WILLIAM AUGUSTUS (1810-1883). — Textbook author and scientist; was graduated from the United States Military Academy at West Point in 1831. He held professorship in New York University, Delaware College, Brown University, and Yale College. He published textbooks on astronomy (1839) and natural philosophy (1858), and made numerous researches in molecular physics and terrestrial magnetism. W. S. M.

NORWAY, EDUCATION IN. — Norway, a constitutional monarchy, having an area of 124,129 7/8 square miles and a population of 2,392,698 (1910). The civil divisions for local government, which are also areas of educational administration, are eighteen counties (*amter*), towns, and rural communes (*herreder*); the latter are generally parishes or subparishes. The capital, Christiania, has a population of 243,801; Bergen has 76,917; and Trondhjem, 45,228. There are all together sixty-one urban communes. During the Middle Ages Norway formed an independent monarchy. In 1397 it entered the Calmar union with Sweden and Denmark, and when the union was broken (1527), Norway remained with the latter. By the terms of the peace of Kiel (Jan. 14, 1814) Norway was transferred from Denmark to Sweden. The union was effected only through the person of the King, Norway retaining its independent legislature. In 1905 the union with Sweden terminated, and the present King, Haakon VII, a son of the King of Denmark, was called to the throne. The Reformed Religion (Lutheran) was introduced into the kingdom in the fifteenth century and has exercised great influence upon the educational development.

Educational History. — Education was originally under the control of the Church, and it was the duty of the parish clergy to see that children were instructed in religion and in letters up to the time of their confirmation. When the constitution of 1814 was adopted, there were four classical (cathedral) schools in the kingdom; but even in these schools the mother tongue was treated as a separate branch, for Norway was never dominated by the classical spirit. An act of 1827 provided that there should be a permanent school near every principal church in the country, and ambulatory schools for isolated districts. There was, however, no marked educational movement before the political awakening in the

third decade of the nineteenth century. Then arose the demand that national culture should reflect national ideals, and that it should rest upon a firm basis of elementary education supported by public authorities. In 1848 an act was passed by the Storting providing for public elementary schools in the towns. This was followed in 1860 by a new act regulating rural schools, and in 1869 by legal provision for continuation schools. These acts were finally replaced by that of 1889, carried by the Liberal party, which pertained to both towns and rural parishes. This measure not only required that elementary schools should be provided, but prescribed in detail the organization and programs of the different grades of schools; for although local authorities are responsible for the establishment and maintenance of schools, the law has left nothing essential to their unlimited choice.

Under the awakened consciousness of national life and needs, the classical schools were the chief subjects of criticism; and the conflict between the older humanities and scientific and modern subjects was worked out through a series of laws and experiments, beginning with the law of June 17, 1869, and culminating in that of July 27, 1896, which determines the present organization of the middle and secondary schools.

Present System. — The national system of education in Norway is similar in many respects to the system of Sweden and Denmark, (*qq.v.*), but places greater emphasis upon practical training and modern subjects. It is noted for the complete provision of schools, for their adaptation to the different classes of society and the close coordination of the several orders of education.

The Department of Education and Ecclesiastical affairs has control of the system. The administration of primary schools is committed to school directors, one for each of the six dioceses of the kingdom. Bishop and Dean take part in the general supervision of the schools, and the clergy may supervise the religious instruction.

The Primary Schools. — In each municipality (town or division of a county) there is a local board (*skolestyret*) which consists of a priest, the chairman of the municipal council (or one of the aldermen), one of the teachers chosen by the body of teachers, and additional members (men and women) chosen by the municipal council. In the towns, at least one fourth of the members so chosen must be parents who have children in the primary schools. The school board, which elects its own chairman, has charge of all the arrangements for the schools of the municipality, *i.e.* choice of sites, building plans, appointment of teachers, etc. Every year the board submits to the municipal council an estimate of the expenditures for the coming year.

The inspection of the primary schools is

intrusted to a committee consisting of one member of the school board as chairman, and three members (men or women) chosen in towns by the parents of the children attending the school, and in the country by parents and the ratepayers in a school district. This committee maintains constant supervision of the schools and of children of school age. The school board and the board of inspection in the country districts may bring the affairs of the primary school before a meeting of the ratepayers of the district and parents of children attending the school, who live in the district. Certain questions must be discussed at the district meeting before they can be decided, *e.g.* whether corporal punishment may be administered, changes in the district regulation, etc. In the large towns, the school board appoints professional inspectors, and where there are several schools, as a rule, a headmaster to each.

For every county, there is a county school board, consisting of three members chosen by the county council. This board has charge of the common educational matters of the county, and makes proposals to the county council concerning the income and the expenditure for county schools.

School Provision — In the country, every district included in a municipality must have a primary school with at least two classes, one for children from seven to ten years of age (infant school), and one for children from ten to fourteen. On account of the distances, the districts in many places are again divided into several infant school districts. In the towns, the primary school is divided into three divisions, intended respectively for children seven to ten years of age, ten to twelve, and twelve to fourteen. Each of these divisions may again be divided into several classes.

School Buildings. — Special buildings must be erected or rented for primary schools. In the country, however, in the infant school districts and in primary school districts that have less than twenty children of school age, school may be held in rotation in the houses of the inhabitants of the district, where sufficient room can be procured. These "ambulatory schools" are steadily decreasing in number.

Program of Studies and Time Allotment. — The subjects of instruction required by law for primary schools and the distribution of time are shown by the table on the following page, which comprises a typical program for a country school of two divisions and for a graded city school.

If optional branches are added to the regular program, instruction in these must be given in extra hours. In the city schools, foreign languages may be included and elaborate provision is generally made for domestic subjects for girls. In the most northerly counties, where the Finns and Laps are found,

NORWAY, EDUCATION IN

their native languages may be used as auxiliary to the Norwegian.

¹ Geometry is taken in the upper classes of the city schools.

The distinctions between city and rural schools illustrate the flexibility of the system. In the country, boys and girls are generally taught in the same class; in the city, in separate classes, with modified programs for the girls. The classes in the country schools should have a minimum of thirty-five pupils and should not exceed forty-five; in the city schools, the range is from forty to fifty. The number of school hours a week in country schools exceeds the number in the city schools; but the annual session in the country is shorter, comprising from twelve to eighteen weeks as against forty weeks in the city.

The standard to be attained by the primary school is fixed by law for religion only. In this subject a thorough knowledge of the main facts of Bible history and Church history, and of the Catechism, according to the Evangelical Lutheran creed, is required. In the other subjects, it is left to the school board to fix the standard; in most of the rural municipalities, however, the standard of the various subjects, and the time-table, are determined in accordance with the "Normal Plan," which after the passage of the act of 1889 was sent out by the Central Department as a guide. Its requirements are indicated by the model time-tables. The examinations and form of leaving certificates are determined by the local boards.

The educational movement in Norway was marked from the first by regard for physical development and training. The Swedish or Ling system of gymnastics was early introduced into the teachers' colleges and adopted in the city schools. Great attention has also been given to hygienic conditions, and the school buildings of Christiania, of Bergen, and

NORWAY, EDUCATION IN

of other populous centers are models in arrangement and in their equipment of baths, of gymnasiums, and rooms for manual training and domestic arts. The spirit and methods of instruction in the schools are also decidedly modern.

Instruction is free in all classes of public primary schools. Needy children receive their schoolbooks and material from the municipality. In Christiania of late years the municipal council has also voted the necessary funds for supplying all needy children with a meal every school day.

Teachers.—Teachers of primary schools are appointed by the local school boards. Both men and women are eligible for appointment, and in town schools there must be one teacher of each sex. Only those can receive permanent appointment who have completed the twentieth year of age, belong to the Established Church, and have passed a teachers' examination. About one third of the situations, however, may be filled on terms of three months' notice, and for these appointments, and for visiting and assistant teachers, no examination is required. There are two grades of teachers' examinations. The lower, which corresponds to the entrance examination of training colleges, covers what is requisite for a permanent appointment in an infant school in the country. The higher teachers' examination, or leaving examination at the training colleges, is required for a permanent appointment in the town primary schools, and in the second division of the country primary schools. The examinations are in charge of a committee consisting of three members, who also inspect the teachers' training colleges.

There are at present ten colleges for the training of teachers for the primary school, of which six are public, one for each diocese, and four private. The public colleges are free. In the private colleges, by the aid of government grants, a considerable number of free students are admitted. Candidates for admission, both men and women, must be at least in their eighteenth year, must pass an examination in the primary studies, and offer testimonials of good character. The course of training covers three years and includes all the subjects taught in the primary schools. To each of the public colleges is attached a one-year preparation class for teachers of infant, or lower primary, schools. The public colleges register about 520 students, the private colleges about 400.

For the training of teachers (men and women) in sloyd, needlework, domestic economy, gymnastics, drawing, singing, and writing, courses are held at longer or shorter interval, according to requirement. Holiday or "continuation" courses lasting five or six weeks are also held for teachers of the primary schools. In these courses, of which there is one in each

NORWAY, EDUCATION IN

NORWAY, EDUCATION IN

diocese, particular attention is given to Norwegian history and natural science, and educational matters are discussed. Since 1894 summer courses of twelve days' duration have also been held annually at the University and at the Bergen Museum; these courses are especially intended to instruct teachers in natural science. The Government votes an annual sum, which of late years has amounted to 10,000 kroner (\$2680), towards traveling scholarships for primary school teachers. Several municipalities also provide traveling scholarships.

Salaries. — The salaries of teachers, which vary greatly in different places, are naturally highest in Christiania. In this city the head teachers receive 2600–3800 kroner (\$744–\$1087), free residence and wood for fuel or compensation for it, calculated at 900 kroner. Assistant men teachers receive 1400–2600 kroner (\$400–\$744); women teachers 900–1500 kroner (\$258–\$429). For the country the minimum salary is in the infant school: fourteen kroner (\$4) for each school week with thirty hours' instruction. In the higher divisions: 18 kroner (\$5.15) for each school week of thirty-six hours' instruction. In addition to this teachers in the country, who give at least twenty-four weeks' instruction in the year, enjoy four increases of salary, each of sixty kroner (\$17.16) yearly in the infant school and 100 kroner (\$28.60) yearly in the higher divisions, after respectively four, eight, ten, and fifteen years' service. Moreover, one teacher, at least, in each commune must be furnished, without charge, a house and a piece of land. Teachers are pensioned by the state.

Statistics of Primary Schools. — The efficient administration of the system is indicated by the large enrollment in the schools, about 370,000 pupils at the latest date reported (1909) or 15½ per cent of the population. Of the total 92,950 were in city schools. The teaching force numbered 8106, of whom 5611 (4183 men, 1428 women) were in the rural schools, or one teacher to every forty-seven pupils; the city schools employed 2495 (856

men, 1639 women), one teacher to thirty-three pupils.

The expenditure for the public elementary schools was 13,047,210 kroner (\$3,731,562), equivalent to \$10 per capita of enrollment and to \$1.54 per capita of population. Of the amount 42.7 per cent went to the support of city schools. The State appropriated 4,256,749 kroner, equal to 32 per cent, of the total expenditure.

Sources of Support. — The State contributes one third of the regular salaries paid to teachers of primary schools. The remaining expenses fall upon the communes and the county funds. The latter, however, are derived from State grants to the amount of three fourths the total; the remaining fourth comes from the county revenues. These funds defray extra expenditures, i.e. increase of teachers' salaries for long services; aid toward the erection of school buildings; and provision of land for teachers or compensation for the same; educational apparatus; aid for poor municipalities; expense for substitute teachers to replace regular teachers in case of long illness; for continuation schools and artisan schools (*arbeidsskoler*).

The annual expenditure from public funds for teachers' colleges (*laererskoler*) not included in the totals above given is about 255,000 kr. (\$73,000). A small proportion of this amount goes to private training colleges.

Schools for Defectives. — Public provision for the education of children is completed by schools for defectives, i.e. the deaf, blind, and imbecile children. This work, which is under a director attached to the central department of education, is regulated by a law of 1881 and subsequent amending laws. In respect to general instruction, the aim of the schools for defectives is the same as that of the primary school; in addition the pupils are educated for a practical life. The school courses extend, as a rule, over eight years. Deaf children are admitted at the age of seven, blind children at the age of nine, and imbeciles, at present, at the age of fourteen or fifteen.

The latest statistics relating to these schools are as follows:—

INSTITUTIONS		PUPILS			TEACHERS		
Classification	Number	Boys	Girls	Total	Men	Women	Total
For the Deaf	5	171	157	328	36	31	67
For the Blind	2	90	52	142	13	10	23
For the Feeble-minded . .	3	259	238	497	20	53	73

The institutions considered are all maintained by the State, which also supports a school for blind adults.

Abandoned and Vicious Children. — By the act of June 6, 1898, which went into effect in 1900, Norway took an advanced position

in regard to neglected children and those who need special restraint. The age of criminal responsibility was raised by this act from ten to fourteen years and it was required that young criminals below fourteen instead of being punished should be brought under moral

influences and properly instructed. Children who commit crimes after having completed their fourteenth year, are liable to punishment; but until they reach the age of sixteen, educational measures may be employed with them. The act is applicable, also, to children who are in danger of becoming burdens to society either as lazy idlers or as criminals and convicts. Such children under specified conditions may be placed in the care of the State. The charge of children who come within the provisions of the act is committed to boards of guardians, formed in every municipality and consisting of a judge, a clergyman, and five members chosen for a period of two years by the municipal council. One of these members must be a medical man living or practicing in the municipality, and one or two must be women.

The boards of guardians have authority to remove a child from his parents and place him in a trustworthy family, or home, or in an institution, such as a reformatory school, or a *skolehjem*. If the board of guardians consider that the child may be left with his parents, they may warn both him and his parents and in certain cases may punish the child as merited.

A reformatory school may be erected by a single municipality or by several in conjunction. Its plan must be approved by the King. Children that are so depraved morally that their attendance at the ordinary school would be injurious to other children may be committed to a *skolehjem*. These institutions are of two classes, one for specially depraved children, and one for the wayward. The former are erected by the State, for boys and girls separately. At Bast, near Christiania, one has been built to accommodate 150 boys. A similar establishment for girls has been founded near Christiania. The more lenient institutions may be private or municipal, but must conform to the legal requirements.

The state charge of children that are removed from their parents ends when the cause ceases and as a rule is not continued after the child has completed his eighteenth year. Children that have been placed in reformatories of the strictest kind may, however, be kept there until they have completed their twenty-first year. The supervision of this class of children pertains to the Ecclesiastical and Educational Department. The cost of the work is divided between the State and the municipalities.

Continuation Schools — Provision for continuing the education of youths and adults after the period for attendance upon primary schools is made by a variety of agencies: the ordinary continuation schools (*Fortsettelsskoler*) with sessions of from one to six months a year are intended for young people, fifteen to sixteen years of age, who have been out of school for a year or two and who wish to review their studies. These schools in 1909 numbered

166 with 2455 pupils (1628 males, 827 females). The expenditure was 68,613 kroner (\$18,388), of which 65 per cent was from public funds. Evening schools, intended for pupils seventeen to nineteen years of age, offer special courses, covering, on an average, instruction for fifty hours in the year. They numbered 569 in 1908 with 8299 pupils (of which 5516 were young men). The expenditure was 52,240 kroner (\$14,940), of which 88 per cent was from public funds.

County schools are similar in purpose to People's High Schools which were introduced from Denmark (*q.v.*). The former, however, which are maintained by public authorities, place special emphasis upon practical or technical subjects, *i.e.* in the schools for men, or mixed schools, upon drawing and sloyd; in the schools for girls only, upon needlework and domestic arts. The teachers of these schools are generally taken from the staff of the primary schools or, for the higher studies, from the force of secondary professors. The annual session is from six to seven months; schools for women only three months. The latest statistics show thirty-nine county schools with 1580 pupils (881 men, 699 women) and fifteen People's High Schools with about 650 pupils; of these a little more than half were men. The state subsidizes both classes of schools.

City evening schools and the county schools in some cases have developed into what are termed Working Men's Colleges. In these institutions adult men and women are instructed in the phenomena of nature, in the duties and relations of social life, and in the progress of knowledge and its industrial results. The first college of this class was erected in Christiania in 1885, and this example has since been followed in several towns and rural districts. The public libraries, which number about 700, cooperate with this work.

Secondary Education. — Public secondary schools are under the general direction of the Department of Ecclesiastical and Educational Affairs. For the inspection of the schools and the arrangement of the leaving examinations, there is a council of seven members competent in matters of higher education; in respect to hygienic matters an expert is called to the assistance of the council.

The public secondary schools are either state or municipal schools. Each of the former is managed by a special board consisting of the head master, one member appointed by the Department, and three by the municipal council. The municipal secondary schools may be managed by the local school board, or by a special board. The principals and permanent teachers of the state schools receive their appointments from the King and are government officials. The municipalities provide the school premises, buildings, and equipments; the current expenses are met by gov-

NORWAY, EDUCATION IN

ernment grants, fees, and endowments. The municipal schools are also supported in part by government grants. Their principals and permanent teachers are appointed by the Department of Public Instruction and their qualifications and salaries are practically the same as for teachers of the state schools.

There are also many private secondary schools of the same standing as the public schools.

By the law of 1896 provision is made for two orders of secondary instruction, the lower based upon the primary school, the higher leading up from the lower to the university. In its complete form, the lower secondary school (*middelskole*) comprises four progressive classes, the course terminating with an examination (*middelskoleeksamen*). This school is coordinated with the second division of the city primary schools, the age for entrance being eleven years; if the school has less than four classes, the age and standard are correspondingly higher.

The gymnasium (higher secondary school) comprises three progressive classes leading to the *examen artium* which is required for admission to university studies. To enter the gymnasium, the applicant must be at least fifteen years old and must have passed the *middelskoleeksamen*. The course of the gymnasium is uniform for the first class, at the end of which there is bifurcation into the modern side and the linguistic-historical side. The latter may include a Latin section, although by the law of 1896 the classical languages (Latin

NORWAY, EDUCATION IN

and Greek) are relegated to the university. In connection with the first class of the gymnasium, or with the lower secondary school, there may be arranged a one year's course for pupils who intend soon to enter business life. Both classes of secondary schools are, in general, coeducational. The girls gain relief from excessive work, either by spending two years in a class or by taking only one foreign language and a short course in mathematics, a privilege accorded to boys also. The programs of the two orders of instruction are shown by the following time-tables:—

Singing									
Number of hours a week	36	36	36	36	36	36	36	36	36

The division of the time assigned to gymnastics and singing is left to the managers of the different schools.

The vacation amounts to twelve to thirteen weeks in the year, of which seven weeks are in the summer. Every school day comprises six periods of forty-five minutes each. Six hours

in the week, as a rule, one hour a day, must be given to physical exercises, manual work, and singing.

Teachers.—The staff of the state secondary schools consists of principals (*Rektors*), head teachers, and assistant teachers, men and women. There are also special teachers for

gymnastics, singing, sloyd, domestic economy, etc. The teachers acquire their theoretical training at the university. The course of training which covers about six years is terminated by an examination (*laerereksamen*). After passing this examination the candidates must take a half-year course at the pedagogical seminary of the university, and are then examined in pedagogics, school method, and psychology. Simultaneously with this course the candidates gain practical experience in teaching at an appointed school.

The salaries are per annum:—

For principals	4600-5400 kr. ¹	(\$1315 to \$1544)
For head teachers	3200-4400 kr.	(\$915 to \$1258)
For assistant teachers	2200-3200 kr.	(\$629 to \$915)
For women teachers	1200-1700 kr.	(\$343 to \$486)

¹ Also free residence.

Statistics of Secondary Schools.—There are 14 state, 5 communal, and 7 private schools having gymnasium classes and authorized to prepare pupils for the *examen artium*; in addition there are 52 schools (45 communal and 7 private) that stop with the middle school examination. The total number of pupils in all classes of secondary schools in 1909 was 17,104, distributed as follows: Gymnasium classes, 1725 (of these 444 were girls); middle schools, 11,435 (girls, 5333); one year preparatory, 3944 (girls, 2252). The number of teachers in the secondary schools was 1313, including 813 men and 500 women.

The expenditure for the public secondary schools of both orders is met by state and local appropriations, endowment funds, and tuition fees. The fees are fixed for each school according to circumstances. In 1909 the expenditure amounted to 2,203,225 kr. (\$630,122). Of this amount the State bore 35 per cent and the local appropriations 16 per cent or a little more than half the whole amount.

In addition to the schools referred to above, there are several municipal and private schools without the examination rights, in which instruction is given beyond the scope of the primary school. These schools have a freer arrangement than the *middelskoler*, and have as a special object provision for the higher education of girls. In 1909 there was one communal school of this class in Christiania with 40 pupils (all boys) and 89 private schools. Of the latter there were, for boys only, 9 schools with 416 pupils; for girls only, 4 schools with 244 pupils; and 76 coeducational schools with 2890 pupils (1634 boys; 1256 girls).

Coördination of Schools and Higher Institutions.—The system of public education is completed by the universities and by special technical schools. The close relation of the various classes of schools to each other, which facilitates the passage from one to the other, is illustrated by the accompanying diagram.

Technical Education.—Technical schools, which are found chiefly in the towns, are of two orders, the lower technical schools which pupils may enter from the elementary school, and a higher order based upon the *middelskole*. The lower technical schools include (1) technical evening schools with three-year courses, comprising annual sessions of 8 months with instruction for 10 hours a week; (2) public drawing schools; and (3) industrial schools for girls with one-year courses in handicraft, and domestic arts. To this order belong also the Christiania Technical School; School of Mechanic Arts of Skien; School for Wood and Metal Work at Bergen. Of a somewhat higher or more specialized character than the above named schools are the following: middle technical schools at Trondhjem, Christiania, and Bergen, having four-year courses and requiring for entrance the leaving examination of the lower secondary schools (*middelskoleeksamen*); an elementary mining school at Kongsberg with a course of two and one half years and twelve hours' session a week (age of entrance, eighteen years); commercial gymnasiums at Christiania and Bergen with courses of two years for men and one year for women; 22 schools of navigation; for the promotion of rural industries the following: agricultural schools, 19; schools of gardening, 16; dairy schools, 6; 1 agricultural high school.

The technical schools of the highest class comprise 6 schools of engineering, and a technical institute of dentistry. For promotion of the fine arts there are two national schools, the Royal industrial art school, and the conservatory of music, both at Christiania.

The University.—The Royal Frederick University at Christiania was founded in 1811, and began its operation in 1813 with 11 professors, 3 lecturers, and 18 students. In 1912 it had 70 professors, 14 "docents," 19 fellows, and 1500 students. The university comprises five faculties, each of which elects its own president, or dean, for a term of two years. The deans form the academic council which constitutes the university's board of management subordinate only to the Ecclesiastical and Education Department. The university professors receive their appointments from the King. The minimum salary is 4500 kr. (\$1206) with three additions of 50 kr. (\$134) each after 5, 10, and 15 years' service. The 20 oldest professors, moreover, have an addition of 60 kr. each. The "docents" are also appointed by the King. The fellows, who have only a limited amount of lecturing to do, are appointed for one year at a time, by the university council.

The gymnasium leaving examination (*examen artium*) is required for admission to the university. The instruction is free, but fees are paid for admission to the various examinations (from \$5.36 to \$10.72). Before students can go up to any of the university degree examinations, they must have passed a preparatory examination, *examen philosophicum*. In this examination, philosophy is a compulsory subject; the five remaining subjects may be chosen by the candidate from science, languages, history, mathematics, etc. The time of preparation for the *examen philosophicum* is 2 or 3 terms. The average time required to work up for the various examinations is as follows: 9 terms for theology; 8 for law; 14 for medicine; 10 for philology, and 10 for "real students." Clinical facilities are afforded medical students in two government hospitals whose head physicians are university professors. Theological students get their special training at a theological college connected with the university. There are various collections, laboratories, and scientific institutions belonging to the university. Among them are the University Library (350,000 volumes) which is also the National Library, with a reading room open to any one for several hours daily; the Botanical Gardens, the Historical Museum, the Astronomical and Magnetic Observatory, the Meteorological Institute, and the Biological Marine Station at Drøbak. The income of the university for 1910-1911 was 910,280 kr. (\$243,955). Of this amount 64 per cent was supplied by the state appropriation. There was also an ap-

propriation of 225,000 kr. for the library and of 7400 kr. for new laboratory buildings.

The principal scientific societies are the Royal Literary and Philosophical Society at Trondhjem, founded in 1760, which has a library of about 7000 volumes, and the Literary and Philosophical Society at Christiania, founded in 1857, with which is associated the Fridtjof Nansen Fund for the promotion of science; the capital of the fund, at present, amounts to about 450,000 crowns (\$120,600). The Bergen Museum, founded in 1825, is a center of scientific activity in the western part of Norway. It possesses valuable collections, especially of natural history, a scientific library, and a biological station with laboratories, aquaria, etc. There are also Museums at Trömsö, Stavanger, and Arendal, with natural history and historical antiquarian collections. For the preservation of "Ancient Norwegian Monuments" there is an association, founded in 1844, supported by a government grant.

The Norwegian National Museum, founded in 1894, at Christiania, collects and exhibits everything throwing light upon the culture life of the Norwegian people. The industrial arts museums at Christiania, Bergen, and Trondhjem possess valuable collections and have had great influence in promoting beauty of design in the embroideries, copper utensils, silver jewelry, etc., for which Norway is noted.

The public expenditure for education in 1909 was 20,307,886 kr. equivalent to \$5,442,514. Of this total the state treasury furnished 8,955,289 kr. or 44 per cent. A. T. S.

NORWICH UNIVERSITY, NORTHFIELD, VT.—The earliest of American military colleges after West Point, was opened at Norwich, Vt., by Captain Alden Partridge in 1820, located at Middletown, Conn., 1825-1829; returned to Norwich in the latter year, and removed to Northfield, Vt., in 1857. It was chartered under its present name in 1834. Its founder sought to enrich the curricula of his day by adding thereto: physical training; laboratory and field practice in science; engineering; agriculture; the mechanic arts; and military science and practice under military discipline. (See *Lecture on Education*, 1819.) Much of this he put into practice at Norwich and some came quickly into use elsewhere, although agriculture and the mechanic arts lagged forty years before they were adopted. Of Norwich students of 1835-1865 living in '61, with records now known, 69 per cent found service in the armies and navies of '61-'65, 58 per cent as officers. The Norwich History, covering the records of its students, evidences the founder's wisdom and foresight in departing from the conventional college plan of his day. The essentials of his plan have been retained but modified as experience has dictated, save that the elective system, which he was among the first to adopt, has long since passed away. According to the history named, the total enrollment to date has been 3853; graduates 809. Students now enrolled number 183; professors 14. The departments of instruction lead to the Bachelor degrees in Arts, in Science and Literature, in Chemistry, in Civil and Electrical Engineering.

DODGE, G. M., and ELLIS, W. R. *History of Norwich University.* (Concord, 1912.)

NOSE, HYGIENE OF THE.—The nose may be called the hygienist or health inspector among the senses. In normal condition it tests the sanitary condition of the environment, of the air we breathe, and the food that we eat. Also it warms and moistens and purifies the air, and nasal respiration is essential to the proper nutrition of the brain. It is certain obvious rules of hygiene are important. Children should be taught proper habits and methods of cleanliness, not to blow their noses violently, and not to put things into them. Injuries to the nose should be attended to; for accidents, blows on the nose, falls from trees or walls or gymnastic apparatus, may cause deviation of the septum.

Anything that causes partial or total occlusion of the nostrils, like injuries to the septum, deformed growth, adenoid growths, hypertrophy of the faucal tonsils, the swelling

of the mucous membrane in colds, or the like, is hygienically a serious matter, since it is likely to cause defects of speech, defects of hearing, interference with the brain activity and with growth and development and the health in general. The most common cause of defective hearing is probably some nasal trouble, especially an adenoid growth. Nasal breathing is of primary importance not only for the health of the pupil but for efficient school work. The improvement in the mental ability after the removal of adenoids (*q.v.*), causing mouth breathing, has been a commonly observed result; and special tests made by the German specialist Kafemann, in which the ability of his subjects to add simple numbers was tested, in one series of experiments with the nostrils open, and in another with the nostrils occluded artificially, showed that the occlusion interfered with the mental activity and less work could be done.

It is important for the teacher to know the essential facts in regard to the hygiene of the nose. A child suffering from adenoids, for example, is liable to be treated unjustly and unwisely on account of irritability or disorderly conduct. The child is likely to be inattentive and backward in school work. Parents may be ignorant of the child's condition, and neglect is likely to mean a serious handicap in mental and physical development, speech defects, constant danger from colds, and ultimately deafness. (See **ADENOIDS**.)

The main points emphasized by recent investigations may be summed up briefly as follows: (1) The hygiene of the nose is of prime importance both for the health of the individual pupil and for the sanitation of the schoolroom; and the obvious rules in regard to cleanliness, care for injuries, and the like are emphasized. (2) Health inspection should always include careful examination of the upper air passages, the nose and naso-pharynx. (3) Nasal breathing is an important condition of efficient brain activity, and occlusion of the nose from any cause should receive special attention. (4) The most common permanent cause of occlusion of the nostrils is hypertrophy of the nasal pharyngeal tonsil, the so-called adenoid growth. This trouble is likely to be found in at least 5 or 6 per cent of the school children in perhaps most of the schools of this country. (5) While there is no consensus in regard to the specific cause of adenoids, the growth is apparently connected with the greater activity of the lymphoid tissue in childhood. (6) Adenoids are apt to occur in the early years before the age of six, and frequently they are found at birth. (7) The operation for adenoids is usually successful; it should not as a rule be performed before the child is six months old; but it is very desirable that the adenoid should be removed at least before the age of six years, in order that healthful development may not be hin-

dered. (8) It is desirable that careful examination of the nasal cavities should be made in the case of all children on entering school life. When adenoids or the like are found, parents should be advised of the condition of their children and the need of proper treatment. (9) No child should be sent to a school for the feeble-minded or the like without first being tested by a competent specialist to determine whether the mental retardation be not caused in part by an adenoid growth. (10) The hygiene of the nose and nasal breathing is of such importance for the actual work of the school that all teachers should be taught the main facts in regard to the subject.

NOSS, THEODORE BLAND (1852-1909) — Normal school principal; was graduated from the Shippensburg (Pa.) Normal School in 1874 and from Syracuse University in 1880. He subsequently studied at the Universities of Jena and Berlin in Germany and Paris in France. He was one of the founders of the Herbart Society in America and was active in movements concerned with the scientific study of education. He was principal of the State Normal School at California, Pa., from 1883 to 1909, having previous to his appointment as principal been an instructor in the institution. His publications include *Outlines of Psychology and Pedagogy* (1890), *Child Study Record* (1900), and numerous articles in educational reviews. He was the editor of *School Year Books*, a series of manuals for teachers in the elementary schools.

W. S. M.

NOTATION. — A word used in arithmetic to mean the writing of numbers, as distinguished from numeration, which is taken to mean the reading of numbers. This distinction is a modern one and is of no particular value, representing as it does the tendency to extreme classification of the eighteenth and nineteenth centuries rather than any educational necessity. Notation comes from *nota*, a word used by medieval writers to indicate a numeral in the Hindu-Arabic system. Thus Clichtoveus (1503 edition) and Tziviw (1507) speak of the *nota circularis* for zero, and Noviomagus (1539) has a chapter *De notis numerorum*.

At present, in the teaching of arithmetic, it is common to speak of Arabic notation and Roman notation, meaning thereby the writing of the Hindu-Arabic and the Roman numerals. There are, however, many numerals besides these, not only those of the past but also those used in many parts of the world to-day. In our American and European schools, however, only these two are taught, and the Roman system is rapidly losing its importance.

Roman Notation. — The late Romans used the symbols I, V, X, L, C, D, and M. They had no generally recognized system for the writing of large numbers, although Pliny and occasionally other writers used a bar over a numeral to increase its value a thousand fold. Thus \overline{X} meant ten thousand. In general, however, large numbers were written out in words. The Romans made some use of the subtractive principle, IX meaning 10 - 1, while XI meant 10 + 1. This principle sometimes extended to a double subtraction, as in the case of IIXX for eighteen (*duo de viginti*). On the other hand, it was rarely used in the case of four, IIII being preferred to IV, as the clock face still witnesses. The subtractive principle appears in the case of XIX for nineteen, but rarely in the case of CD for 400, the Romans preferring CCCC. The form MCM for 1900 is purely modern, the Romans using MDCCCLXXX.

The origin of the Roman notation has been a matter of much speculation. In general, however, the symbols are thought to come from certain Greek letters that were not used in making up the Latin alphabet. In particular, L is thought to come from Ψ , C from Θ , and M from Φ . D (for 500) is half of the early form for 1000. Possibly V was suggested by a cancel mark across IIII, and X is two V's; or X may be derived from crossing out ten I's, and V may be half of it. This latter seems probable, since the five is occasionally found as an inverted V, thus: A. There are various other theories, but nothing in the early inscriptions thus far known has developed anything definite beyond the one above given.

The late Roman numerals differed considerably from those of the classical period, as

NOTATION

is seen from the following table from the *Mysticæ numerorum significationis liber* of Bungus (Bongo), published at Bergamo in 1583-1584.

The Hindu-Arabic Notation. — What are commonly called the Arabic numerals are of Hindu origin. The earliest trace we have of them is in certain inscriptions of the third century B.C., cut on stone in India in the time of King Asoka. The following table shows some of the earliest forms:—

	1	2	3	4	5	6	7	8	9	10	20	30	40	50	60	70	80	90	100	200	1000
c. 250 B.C.	I	II	III	IIII																	
c. 100 B.C.	I	II	III	IX	XX	XX	XX	XX	XX	XX	XX	XX	XX	XX	XX	XX	XX	XX	XX	XX	XX
c. 250 B.C.	I	II	+	+																	
c. 150 B.C.	—	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+
c. 100 B.C.	—	≡	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+
c. 200 A.D.	—	≡	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+
c. 150 A.D.	—	≡	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+
c. 350 A.D.	—	≡	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+
c. 600 A.D.	—	≡	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+

It will be observed that the zero does not appear, but that separate symbols for 10, 20, and so on are necessary. This was the case in many ancient systems of notation.

Without the zero it is impossible to have a place value, and since the oldest inscription in which the place value is evident dates from 595 of our era, we may say that the zero was a product of the sixth century. The earliest

NOTATION

undoubted inscription in which zero appears, however, is found in Gwalior, India, and dates from 876 of our era, although there is one manuscript that probably antedates this in which a dot is used for zero. By the time the place value was established the numerals had changed to such forms as the following:—

	1	2	3	4	5	6	7	8	9	0
a	1	2	3	4	5	6	7	8	9	0
b	1	2	3	4	5	6	7	8	9	0
c	1	2	3	4	5	6	7	8	9	0
d	1	2	3	4	5	6	7	8	9	0
e	1	2	3	4	5	6	7	8	9	0
f	1	2	3	4	5	6	7	8	9	0
g	1	2	3	4	5	6	7	8	9	0
h	1	2	3	4	5	6	7	8	9	0
i	1	2	3	4	5	6	7	8	9	0
j	1	2	3	4	5	6	7	8	9	0
k	1	2	3	4	5	6	7	8	9	0
l	1	2	3	4	5	6	7	8	9	0
m	1	2	3	4	5	6	7	8	9	0
n	1	2	3	4	5	6	7	8	9	0

It is uncertain when the numerals began to be known in Europe, but by the tenth century they had reached Spain and probably were somewhat known in Italy. The forms at this period differ somewhat from those of India, as may be seen from the table on the following page.

Among the earliest writers of prominence to recognize the value of these numerals was Fibonacci, Gerbert, and Sacrobosco (*qq.v.*). After printing from movable type was invented, in the fifteenth century, the forms of the numerals, like those of the letters, became quite definitely fixed, although there is still some variation in different countries, particularly in the written notation.

Scales of Notation. — Our common system of notation is based upon the scale of ten. For example, 2405 means 5 units + 0 tens + 4 times the square of 10 + 2 times the cube of 10. This comes from the fact that we have ten fingers, and the fingers formed the primitive abacus. (See ABACUS; FINGER RECKONING.) It is apparent, however, that systems of notation might be devised on various

NOTEBOOK METHOD

NOTKER

EARLIEST MANUSCRIPT FORMS

[illegible]

scales. For example, if the scale of twelve were selected, we should need two more numerals, say t for ten and e for eleven. Then the number $9t3e$ would mean $11 + 3 \cdot 12 + 10 \cdot 12^2 + 9 \cdot 12^3$, and this would be 17,039 on our ordinary scale of ten. In some respects the scale of twelve would be more convenient than the scale of ten. For example, when we reduce the most commonly used fractions to decimal forms we have: $\frac{1}{2} = 0.5$, $\frac{1}{3} = 0.3333$ +, $\frac{1}{4} = 0.25$, $\frac{2}{3} = 0.6666$ +, $\frac{3}{4} = 0.75$, $\frac{1}{5} = 0.125$, and so on. But these fractions are expressed more easily on the scale of twelve, thus: $\frac{1}{2} = 0.6$, $\frac{1}{3} = 0.4$, $\frac{1}{4} = 0.3$, $\frac{2}{3} = 0.8$, $\frac{3}{4} = 0.9$, $\frac{1}{5} = 0.16$, and so on.

Educationally, the study of different scales of notation has no place in the elementary school. It is an interesting generalization in algebra, but its value to the average pupil is easily exhausted. D. E. S.

SMITH, D. F., and KARPINSKI, L. C. *Hindu-Arabic Numerals*. (Boston, 1911.)

NOTEBOOK METHOD.—Many secondary schools and some elementary schools are placing an increased emphasis upon the notebook as a means of recording observations and readings in history, geography, nature study, elementary science, and other subjects. It is a successful device for holding the student responsible for results and for directing him toward definite and accurate impressions and ideas. As a method, given undue importance, its use possesses several distinct dangers. The pupil may become mechanical in the

recording of notes, without bringing reflection to the organization of his experiences; his note-taking may become a mere copying of the statements of teacher or text, and lead to waste in recording facts which are unimportant save as preliminaries in obtaining fundamental conclusions.

H. S.

NOTION.—The term is closely related to the term idea, but usually refers to an idea which is not clear, or to that aspect of an idea which is not explicit. One says that he has a notion of what the author means, but no clear idea. The term is very little used in technical writings. C. H. J.

NOTKER — The family name of a number of famous scholars of the Middle Ages, all of whom are probably related to one another. The earliest of these was *Notker Balbulus*, or the Stammerer (c. 840-912), who was educated at St. Gall and there studied Greek, Latin, music, poetry, and the Scriptures. He became master of the school and for a time was librarian. He was the composer of poems and songs, including, it was thought, the anthem *Media Vita in Morte Sumus*, and introduced the sequences into Germany. He was the teacher of *Notker Physicus*, who showed great ability in music, painting, writing, and medicine, and won favor at the court of Otto I.

The most famous member of the family was *Notker Labeo*, or the Thick-lipped (c. 950-1022), a nephew of Ekkehard I. He was a good student of music, poetry, mathematics, astronomy, the Scriptures, the Church Fathers, the classics, and the vernacular. He was regarded as the greatest scholar of his day, but his chief title to fame was his encouragement of the use of the vernacular. He himself translated a number of works into Old High German, e.g. Boethius, *De consolatore philosophicæ*; Aristotle, *De nuptiis Philologiae et Mercurii*; Capella, *De categoriis*, the *Psalms*; Terence, *Andria*; Vergil, *Eclogues*. He was also the author of an essay in German on musical instruments. The surname Teutonicus was given to him in recognition of this work. In a letter found at Brussels Notker recommends the study of the classical works as a preparation for the study of ecclesiastical writings, and urges the translation into the vernacular for greater ease of comprehension.

Of greater influence than his predecessors was *Nokter* (c. 940-1508), Bishop of Liège formerly Provost of St. Gall, with which he seems always to have been in touch. He was an enthusiastic teacher and was always surrounded by a group of scholars over whom he exercised an excellent influence and to whom he willingly gave his books. Pupils flocked to the Cathedral School at Liège, where provision was made for externs or lay students, and interns, or students who looked to the priesthood, whither they were sent by the

NOTRE DAME, SCHOOL SISTERS OF

parents and clergy. Liège thus became a center from which teachers were sent to most parts of northern Europe. Of the pupils who had studied under Notker seven attained to bishoprics.

NOTRE DAME, UNIVERSITY OF, NOTRE DAME, IND.

— One of the most famous Catholic institutions of higher learning. It was founded in 1842 by the Very Rev. Edward Sorin and was chartered in 1844 by the Legislature of Indiana. The University is conducted by the Congregation of the Holy Cross. Until 1865 only a college of arts and letters was maintained. In that year the college of science was added. In addition there are colleges of engineering (1872), architecture, and law (1869), and a preparatory school. Students are admitted to the college after graduation from a four-year high school. The usual degrees are conferred on undergraduate and graduate students on completing the appropriate courses (three years in the college of law, four years in the other colleges). Twenty buildings, valued with their equipment and apparatus at \$2,800,000, are devoted to university purposes. From the University Press is issued *The Ave Maria*, a literary and religious magazine with contributions from the best writers in Europe and America. Notre Dame also awards each year the Lactare Medal to some Catholic layman for distinction in some branch of learning. The faculty consists of 85 members. In 1911–1912 the enrollment of students was 987.

NOTT, ELIPHALET (1773–1866). — College president; was born at Ashford, Conn., June 25, 1773. He was privately educated and was graduated from Brown University in 1795. For two years he was principal of the academy at Plainfield, Conn. Later he went as a missionary to Cherry Valley, N.Y., where he established an academy and served as both pastor and teacher. After a brief pastorate at Albany he accepted in 1804 the presidency of Union College, which he held until his death. Although the institution was established nine years before he became its president, Dr. Nott was the virtual founder of the college. He was a member of its board of trustees from the first; and it was during his administration that it rose to collegiate

NOTTINGHAM

rank. The engineering school, the medical school, and the Dudley observatory were organized during his administration. The discipline of the college under his presidency was parental. He made military drills a feature of the collegiate work for purposes of physical training; and he introduced courses in gardening and agriculture. He was active in the organization of the American Association for the Advancement of Education (q.v.), and was its second president. In addition to his participation in various national and state educational movements, he was an ardent advocate of temperance, antislavery, and religious and civil liberty. He was a student of applied physics all his life, and secured patents on thirty different scientific devices. One of these was the first stove used for burning anthracite coal. His publications include *Counsels to Young Men* (1845), *Lectures on Temperance* (1847), and numerous pamphlets and addresses. He died at Schenectady, N.Y., Jan. 29, 1866. W. S. M.

NOTTINGHAM, UNIVERSITY COLLEGE, ENGLAND.

— An institution founded in 1881 by the "Mayor, Aldermen, and Citizens of Nottingham for the advancement of university learning." A higher literary and scientific education is provided for students over sixteen years of age. A Royal Charter of Incorporation was obtained by the college in 1903. The following departments are maintained: language and literature, including most of the "arts" subjects; chemistry and metallurgy; physics and mathematics; natural sciences; engineering. A Day Training Department is maintained in connection with the Board of Education. In the technical branches, courses with a special bearing on the local lace and hosiery industry are provided. There are no conditions of admission beyond general fitness to profit by the courses.

The College does not grant degrees, but prepares students for the examinations of the University of London. The title of Associate of University College, Nottingham may, however, be conferred. The College also has power to grant a diploma in mining engineering. The majority of the students are enrolled in the evening classes. The enrollment in 1910 was 607 day and 1718 evening students. The College receives grants from the Treasury, the Board of Education, the Nottingham City and County Councils, and subscriptions for special purposes from many private sources, e.g. the Drapers' Company.

NOWELL, ALEXANDER (?1507-1602). — Dean of St. Paul's and educationist of Queen Elizabeth's reign, born at Read Hall, Whalley, Lancashire. Alexander was educated at Middleton, near Manchester, and "entered Brasenose College at the age of thirteen (i.e. 1520); he resided there thirteen years; and he afterwards bestowed on the society thirteen scholarships." He is said to have taught the textbook of Rudolphus Agricola at twenty years of age. In 1543 he became Master of Westminster School, described as being then "the chief seminary in the kingdom," which post he held till 1555, when he was succeeded by Nicholas Udall (*q.v.*). Nowell was diligent in teaching Terence for "pure language" and the original Greek of St. Luke's Gospel and the Acts of the Apostles for "true religion." Nowell was made a Prebendary in Westminster Abbey, and in 1553 was elected M.P. for Leo in Cornwall, from which position he was required to retire on the ground of "having a voice in the Convocation-house." After a few years in exile during Mary's reign, he returned and was made Dean of St. Paul's. Nowell was a consulting educationist in the establishment of schools. The Skinners' Company School at Tonbridge (established by Sir Andrew Judd) brought their statutes for revision to Nowell. He himself founded a grammar school at Middleton in Lancashire and provided scholarships at Brasenose College, Oxford. He drew up the statutes for the organized Friars school at Bangor, and nominated the schoolmaster at Colchester. He himself was actually principal of Brasenose College, Oxford, for a short time. But, as an educationist, Nowell's name is most closely associated with the catechisms which he drew up and presented to Convocation in 1562. These seem to have been three in number; a larger one suitable for Universities drawn up at the suggestion of Lord Burleigh, which summarized the doctrines of the Church of England, was written in Latin, and first printed in 1570. This was translated into English by Thomas Norton in the same year, 1570. The middle (size) catechism was also published in Latin in 1570 and translated into English by Thomas Norton in 1572. The *Catechismus parvus* was published in 1572. All the sizes were translated into Greek by William Whitaker. The small catechism of Nowell took its position in the school manual of religion as the chief and was used in the English schools of the sixteenth and seventeenth centuries. F. W.

NUMERALS. — See NOTATION.

NUMBER — The primitive idea of number was that of a collection of units, unity itself being excluded. (See UNITY.) It was not until about the opening of the seventeenth century that the view of unity as the source of number, but not itself a number, was modified. This is only one of many extensions of the primitive idea, others being seen in the gradual inclusion of fractions, irrational numbers, complex numbers, transcendental numbers (*qqv*), and so on. There is no satisfactory elementary definition of number that covers all of the possible types, but Newton's definition of number as the ratio of one quantity to another quantity of the same kind answers the purposes fairly well. Thus the ratio of 4 ft. to 1 ft. gives the positive integer 4, and its reciprocal gives the positive fraction $\frac{1}{4}$. The ratio of the diagonal to the side of a square gives the irrational number $\sqrt{2}$, and the ratio of a circle to its diameter gives the transcendental number π .

The distinction between abstract and concrete number is modern, number being essentially abstract in any case. In the sixteenth century the distinction appears in several works. Trenchant (1566), for example, speaks of the absolute or abstract and the denominate number (*L'absolu . . . abstrét et le dénommé*). In his category of denominate numbers he included not only 3 ft., but 3 fourths ($\frac{3}{4}$). (See DENOMINATE NUMBERS.)

One of the oldest classifications of numbers is that based upon finger symbolism. (See FINGER RECKONING.) Numbers were divided into digits (fingers), articles (joints), and composites. In the geometry attributed to Boethius (*q.v.*) these three classes are said to be due to "the ancients" (*veteres appellare consueverunt*). They do not seem to have been known to Pliny (*q.v.*) and Apuleius, however, because they both speak of finger symbolism, but make no mention of these names. The digits were the integers from one to nine, that is, below the "first limit" (*infra primum limitum*), which was ten. Since, however, one was not considered a number, the digits were often considered to be only eight in number, as by Peletier (1549), who says: "ce sont les huit figures, 2, 3, 4,

NUMBER

5, 6, 7, 8, 9." It is only in relatively modern times that the word has come thus to be used to represent the characters instead of the numbers themselves. Gemma Frisius (1540), for example, uses digit to mean a number, the figures being called characters or elements (*characteres siue elementa*).

The articles were the multiples of ten, sometimes limited to nine in number (10, 20,

... 90), but usually unlimited (*et in infinitum progressi*, as a work often ascribed to Boethius gives it). Articles were later called "decimal numbers" (*nombre desenal*, Pellos, 1492; *lo numero decenal*, Ortega, 1515), and as such they finally disappeared.

The composites were numbers composed of articles and digits, as 17, 48, 256, etc. The word, however, had another meaning; namely, that of a number that is not prime. This latter meaning finally dominated the other, and is the one now recognized. On account of this double meaning some writers of the sixteenth and seventeenth centuries spoke of a digit plus an article as a mixed number (*q.v.*) or a compound number (*q.v.*), terms that have since been applied to other forms of number.

The oldest known manuscript on arithmetic in the English language, perhaps of c. 1300, has this classification: "Some numbur is called digitus latine, a digit in englys. Somme numbur is called articulus latine. An Articul in englys. Some numbur is called a composyt in englys." This classification was found in most of the medieval books on theoretical arithmetic, but was usually wanting in the commercial works. It was unwieldy, because it allowed for only eight or nine digits, but an unlimited number of articles and composites. Many attempts were made to avoid the difficulty, with two resulting plans: (1) to drop the whole thing, as Leonardo of Pisa (*q.v.*) did at the opening of the thirteenth century, recognizing, as Ramus (*q.v.*) did much later, that it was puerile and fruitless (*puerilis et sine ullo fructu*), or (2) to attempt to classify the infinite number of composites. The latter plan was followed by Sacrobosco (*q.v.*) in the thirteenth century, who elaborated the classification of limits, but did not produce a system that any one seems to have understood.

For other forms of number see the following special topics. FIGURATE NUMBERS; FRACTIONS; IRRATIONAL NUMBERS; MIXED NUMBERS; NEGATIVE NUMBERS. D. E. S.

NUMBER FORM

NUMBER FORM. — A mode of imaging numbers, peculiar to some individuals. Most individuals, in thinking of numbers, make use of various forms of mental imagery, differing according to their individual types, as, for example, visual, auditory, or mixed. Those who use number forms are visualists, who arrange the numbers in a definite spatial order with reference to each other, and with each

number occupying a definite spatial position. The spatial relationships which the numbers thus assume are various, but the form always remains the same in the same individual. The figure shows two such number forms, the first of which was used by a student and the second of which was substituted for the first at a later period. It has been held that thinking of numbers in such

concrete terms is an awkward mode of conceiving the number relationships, but those who use number forms assert that they are very useful, particularly in connection with the keeping of engagements and the remembering of dates in history, etc. Similar forms are often used in connection with the thinking of the days of the week, months of the year, and the seasons. There is some evidence to show that the tendency to think in terms of such

forms is inherited, as the tendency seems to be common to members of the same family. In general, these phenomena may be grouped under the class of phenomena called *synæsthesia*. *Synæsthesias* are held by some authorities to be more frequently found in adolescents than persons of other ages. E. H. C.

NUMBER, PSYCHOLOGY OF.—Psychologically there is a stage of evolution of consciousness of quantity which precedes the development of the number idea. One recognizes the presence of all the articles of furniture in his room, or the withdrawal of familiar articles, without going through the elaborate process of counting. Animals are able to recognize that one of their young has been taken away without being able to count. This direct recognition of quantity is, however, very limited. As soon as the objects grow at all numerous a special system of one to one designation must be developed or the individual object will be lost in the mass. This necessity of marking the objects in large groups undoubtedly furnished the practical motive which drove primitive man to the use of his fingers and to the use of pebbles, shells, or other devices for counting.

After a number system was developed, the next stage of development consisted in the discovery of number relations. Given three objects and two objects, there is always a like result from the bringing together of the two groups. The discovery of the relations of numbers was a slow process. The ancient Greeks were greatly interested in certain characteristics of number groups and built up a body of speculative philosophy around such simple matters as the indivisibility of prime numbers. In sharp contrast, however, to their large contributions to geometry, they did not contribute to the technique of number manipulation to any great extent.

The slow evolution of number ideas in the western world is due in large measure to the clumsy and unsuggestive terminology which grew up especially in the written symbols.

From a purely psychological point of view, one further general consideration may be pointed out. It is often urged that number problems be made concrete, that the interests of children in the schools may be aroused by combining number work and shop work. Indeed, some have gone so far as to suggest that number operations be allowed to arise incidentally out of school work, the number work being motivated by the necessities of measurement which confront the pupil. In reply to

these proposed reforms, it is to be pointed out that the number idea is an abstract idea, different in character from the idea which is derived directly from the inspection or manipulation of any object. The number idea develops by the cultivation of a technique of number operations wholly different in character from the technique of direct constructive manipulation. That this abstract, highly developed system of ideas will ever grow up incidentally is an idle hope. Number consciousness must be carefully cultivated, and number operations must be mastered by a concentration of attention on these operations. No amount of illustrative material will give rise to number ideas. C. H. J.

NURSERY.—See INFANT EDUCATION; KINDERGARTEN, NURSERY RHYMES, also CHILD PSYCHOLOGY.

NURSERY RHYMES.—Those rhymes, ditties and jingles, rhythmic stories and nonsense verses that have been recited or sung to children time out of mind. The most universal of them are sporadic and have grown out of the universal personal relation of mother and child—others are the debris of ancient folklore, bits of old ballads; rhyming, and therefore easily remembered, riddles, proverbs, etc., that have caught the ear of infancy. The unerring instinct of mother, nurse, and child has seized upon those scraps and snatches which were best suited to the awakening senses of the infant and without knowing that they were obeying a great psycho-pedagogical law mothers and nurses have for centuries been stimulating the sense of rhyme and rhythm, and exciting the wonder, fancy, and imagination of the children, with the material that awakens the best response and has the greatest educative value at the infant stage.

The elements in them which are so attractive to the infant ear and mind, are doubtless, first of all, the rhyming jingle, as in *Higgledy piggledy my fat hen*; then, perhaps, the nonsense

surprises, as in *Hey diddle diddle the cat and the fiddle*; *Three wise men of Gotham*; *I'll tell you a story about Jack a Nory*; and then the dramatic action as in *Little Miss Muffet* and *Little Jack Horner*. The most popular with children are generally those in which all these elements are most markedly present.

While no one knows when or where the majority of these nursery rhymes originated, many of them can be traced back to their sources; but it would overstep our space to attempt to point them out. Halliwell indicated the origin of several, but many more have been traced since he wrote. As most of them have been handed down by word of mouth for centuries, there are many variants of them to be found among English-speaking people everywhere, and the part of England from which the early settlers of certain sections of the United States came may often be suggested by the variant of a nursery rhyme which prevails among them to-day.

Early Collections of Nursery Rhymes. — Orally current for centuries, this "light literature of the infant scholar," snatches of which are caught in the literature of all the ages, was not collected in English until about the year 1756, when John Newbery, Oliver Goldsmith's friend and publisher, brought out in London *Mother Goose Melody, Sonnets for the Cradle, in Two Parts*. "Part I," ran the title, "contains the celebrated songs and lullabies of the good old nurses calculated to amuse the children and to excite them to sleep; Part II, those of that sweet songster and nurse of wit and humor, Master William Shakespeare, embellished with cuts and illustrated with notes and maxims, historical, philosophical, and critical." It was almost immediately afterwards reprinted by Isaiah Thomas, the famous printer of Worcester, Mass.

The immediate source of the name *Mother Goose* is to be found in *Les Contes de ma Mère l'Oye* — the title which Charles Perrault chose for his collection of fairy tales published in French in 1697. These were not published in English until 1729, but *Moeder de Gans* and *Mother Goose* were already familiar in nursery rhymes which had been orally current for many years, and John Newbery appropriated the name *Mother Goose* for more than one of his little books.

At the time this book was compiled Oliver Goldsmith was in the constant employ of the publisher Newbery, editing his little books, concocting his advertisements, writing his prefaces, devising his title pages, etc.; and there is little doubt that he and Newbery made this collection together. The nursery rhymes are annotated in a jocosely and sometimes rather coarse style that would hardly suit modern tastes.

This collection went through a few editions in England and in America and then, under the influence of the dreary tendencies of the

time, the nursery rhymes were neglected for a long period in books, though they continued to live in the hearts of the children and in the hearts and minds of their mothers and nurses.

Some of them, however, were from time to time appended as "fillers" to other little books by Newbery and other publishers of books for children who immediately succeeded him, and Joseph Ritson published in 1810 a collection of them under the title of *Gammer Gurton's Garland, or the Nursery Parnassus, a Choice Collection of Pretty Songs and Verses for the Amusement of all Little Good Children who can neither read nor run*.

With the beginning of the interest in folklore the nursery rhymes naturally attracted the attention of students and collectors, and in 1841 Halliwell printed his first collection for the Percy Society. Halliwell has enriched his collection of these rhymes and jingles with many valuable notes, and his book has been the storehouse from which all the later collections of nursery rhymes have been taken. Although he utilized the collections already made, there is no doubt that many of the rhymes in his book were collected for the first time from oral tradition, as his collection is much larger than any other. But the Newbery book was evidently unknown to him or to Ritson, as neither of them makes any reference to it in his preface. It was really not until 1844, or thereabouts, that the collection took strong hold of the American people, although, of course, the rhymes had been imported into the country and were orally current here, as in the mother country, from the earliest colonial days. The Boston editions of Monroe and Francis, issued between 1824 and 1860, have probably tended more than anything else to keep *Mother Goose* alive in this country. The most complete edition, which included Halliwell's notes and nearly all the illustrations that had been made up to that time for *The Nursery Rhymes*, called the Camden Edition, and compiled by Mrs. Valentine, was published sometime after the latter date. It is now out of print and scarce.

An absurd story was set on foot in the preface to an edition of the nursery rhymes published in 1877 to the effect that *Mother Goose* was a Boston woman and that she wrote and her husband, a printer, published the first collection of the nursery rhymes in 1719. The story is based on the statement of some one who thought he had once seen a fragment of such a book, but no one else ever saw or heard of it. Mr. W. H. Whitmore's *The original Mother Goose Melody*, 1892, tells all that can be told of the story and utterly explodes the myth of a Boston *Mother Goose*.

Analysis. — The best way, perhaps, to study the range of the English nursery rhymes in order to get a view of their educational value and interest, is in certain divisions and groups which to some extent follow the progress of the

development of the perceptions and interests of the children. (I) The Mother-play division contains those nursery rhymes which grow out of the intimate personal relationship of mother and child: the groups in which are the lullabies, cradle songs, slumber songs, etc.; the finger plays and other games of mother and child. (II) The Mother-stories division comprises stories about animals; stories about other people; the times, seasons, etc.; rhyming ABC's; proverbs and riddles; paradoxes, etc.; cumulative stories. (III) The Child-play division includes counting-out rhymes and children's games.

The Mother-play Division. — The first thing the baby hears is the *lullaby* or the *cradle song*, such as *Hush a bye, baby*, etc. — The earliest nursery rhymes said or sung to the infant are accompanied by movements and gestures; the sense of touch is used to aid the memory. Some of these are called *finger plays*, such as *Pat a Cake, Pat a Cake; Tickle ye, tickle ye in your hand; Brow Bender; Dance Thumbkin, dance*, etc.; and with their appropriate movements they are among the first games that awaken childish glee. The feet as well as the fingers figure in some of these, such as *This little pig went to market*.

Froebel, the founder of the kindergarten, first made definite educational application of these plays and tales. The first collection of these, the *Mutter- und Koselieder*, was published in 1844. (See further, FROEBEL and KINDERGARTEN.)

Other rhyming games with movements in the division of mother plays are the *Dancing and Seesaw* rhymes, such as *Dance, little baby; See-saw seeradown; Ride a Cock-horse*, etc.

The Mother-stories Division. — In this division children early make acquaintances with animals and their doings as in *Ding Dong Bell; Three Little Kittens; I love Little Pussy*; etc. Stories about other children and the doings of older folk such as *Little Boy Blue; Robin and Richard; Jack and Gull; Little Tom Tucker; Tom, Tom, the Piper's Son* form another considerable group. The flight of time, days and nights, weeks, months, and years, the sun, moon, and stars, the seasons and the weather, etc., furnish subjects for another, which may be illustrated by *Cock Crows in the Morn; March Winds and May Flowers; Thirty Days hath September; Rainbow at Night*, etc. The most typical of the rhyming ABC's, of which there are several, is *A was an apple pie*; of the riddles, *Two legs sat upon three legs; Old Mother Twitcheit*; of the proverbs, *See a pin and pick it up*; of the paradoxes, *Three children sliding on the ice; There was a man of our town; If all the world was apple pie; There was an old woman and what do you think? The man in the wilderness asked me*. The cumulative stories, of which *This is the house that Jack built* or *The Old Woman and her pig* may be taken as the type, are among the oldest known in this group. No form of narrative is so easy to re-

member as this, — and it is small wonder that it is one which particularly appeals to the child.

The Child-play Division. — The third division into which the nursery rhymes fall, that of *child play*, embraces the important group of "counting-out rhymes" in which the fingers are employed; of these there are literally hundreds, each with countless variations in different districts. Familiar examples are *Eeny, meeny, miny, mo; Intery, mintery, cutery, corn; Eena, deena, dina, duss; Handy, pandy, Jacky, dandy; Onery, two-ry, ickery Ann*. The subject of the rhymes of this class has been very fully treated by Mr. H. Carington Bolton in his *Counting-out Rhymes of Children* (London, 1888). This group also includes dramatic games and games of skill and chance. Miss Alice B. Gomme in her *Study of Children's Games* has classified all the dramatic games under the incidents which show the customs and rites from which the games have descended. The customs shown in the games are, among others, those connected with marriage, love, and courtship, funerals, harvest, well worship, tree worship, foundation sacrifice, witches, child-stealing, and divination. There are contests between two rival parties for the taking of prisoners and the possession of ground territory, and contests between animals of prey and their victims; those games dealing with marriage, love and courtship, funerals, and harvest, are the most popular and the most widespread. Among these games may be mentioned; *Nuts in May; Here we go round the Mulberry Bush; London Bridge; Orange and Lemons*. The guessing game of *Buck, buck, how many fingers do I hold up?* through the modern Italian *mora* has been traced to ancient Greece.

Distribution of the Nursery Rhymes. — The nursery rhymes furnish a rich field of study from the historical and sociological point of view, the point of view of the folklorist, and many others, but their chief interest to the educator lies in the foregoing presentation. It may, however, be instructive to glance at the remarkable distribution of the nursery rhymes all over the world. Every nation has its nursery rhymes and jingles and there is a very close family resemblance in all of them. Counterparts of many of our English nursery rhymes are found among the ancient Hebrews, the Zulus of South Africa, and the Indians of North America. The closest resemblances are to be found among those nursery rhymes which are concerned with things personal to the mother and child, the lullabies, the finger play and dancing games, and the stories of the cumulative order. Those in the other divisions differ somewhat in scheme and general idea, and still more in detail, especially as we approach the didactic rhymes, alphabets, proverbs, riddles, and paradoxes. National characteristics, religion, climatic and other conditions, of course, are responsible

for many divergencies of detail. *L'Amour and Rondes du Mariage*, the dancing rhymes and games play a far more important part in children's rhymes and games of the continent of Europe than in our more Puritanical collection. The devil and the evil eye figure very frequently in the nursery rhymes of Southern France and of Italy, and these bristle with allusions to the method of warding off the effect of the *jettatura*, such as, for example: *Si tu rencontras le diable? Je lui ferai mes cornes*. The game of honeypots as played in France has a religious and a superstitious side as well. It is the good God who comes to buy a pot of flowers; when the selection is made, the one who is selected is treated as in the English game, the devil is supposed to get the one God does not buy, and all the others make the sign against the evil eye as they chase him away.

But perhaps these national characteristics are more markedly shown in all languages in the children's riddles and counting-out rhymes. The riddles, many of them, play on the same words and subjects as do ours; others deal with matters of which we do not openly speak, especially among our little ones; most of the counting-out rhymes are constructed upon pretty much the same plan as our own familiar groups already cited, and are as numerous and varied; some of them also contain things which we could not tolerate, and God and the devil, priests and nuns constantly figure in them.

The German *Kinder-reime, Liedchen, Spiele, and Märchen* are, as might be expected, more fantastic and fanciful, and thus approach more nearly to the character of the Swedish and Danish, which have a peculiar sweetness, grace, and charm. The children of Holland and the Flemish folk have a very wide range of traditional nursery literature, and in sound and in sense they approach very closely to those of England. The characteristics of the people of the olden times come out here very strongly. Eating and drinking and wife-beating figure prominently in them, and ships and cows and sheep take the place of other objects which figure in the rhymes of other countries.

There are probably more nursery rhymes in China than can be found in England and America. Mr Isaac Taylor Headland has in his possession over six hundred, collected, for the most part, in two out of eighteen provinces. In many of these rhymes there are features common to our own Mother Goose.

NURSES, CHILDREN'S.—INFANT EDUCATION.

NURSES IN SCHOOLS.—See MEDICAL INSPECTION OF SCHOOLS; CONTAGIOUS DISEASES.

NURSING, EDUCATION FOR.—**HISTORICAL.**—Among the occupations of women, nursing ranks among the oldest. It is indeed hardly possible to conceive of a time in human history when mothers did not care for their children and for the sick and helpless of their families. The slowly accumulated skill and knowledge thus gathered through the experience of primitive women, and passed down by tradition to successive generations, built up the rudiments of primitive nursing, which, mingled with those superstitions which have ever clustered about the sick bed, became a substantial part of the basis of primitive medicine. The records of ancient civilizations, Egypt, India, Greece, Rome, show the growth of medical and sanitary knowledge, discuss physicians of various types, describe hospitals, and lay down elaborate procedures for the care of the sick. There is little mention made of nurses, but it seems probable that certain nursing services were rendered by the "temple-women" or "priestesses," since it was the common custom to bring the sick to the temples for healing, where religious ceremonial could be combined with practical measures of care or treatment.

Between the nurses of the pre-Christian era and our own the historical links are broken, but there is a continuity of record from the days of the early Christian workers down to

the present time. With the diaconate of the early church, the history of Christian nursing begins, and from the earliest apostolic days the care of the sick and poor was placed in the hands of deacons and deaconesses, who were consecrated by the church and ranked with the clergy. Their chief functions were to visit and care for the sick in their homes, to assist the needy and to comfort the afflicted. They also brought the sick with them into their own homes to be cared for. The order grew steadily, spread far and wide into other countries, and lasted for several centuries. Eventually it became so strong that restrictions were placed upon its activities and freedom; it was brought into stricter subjection to the clergy, declined in importance, and was finally abolished altogether in the sixth century.

The order of deaconesses may well be looked upon with respect, as having laid the foundation not only of nursing but of modern works of charity. It was replaced by monastic communities which had in the fifth century become numerous and important, and were already exercising guardianship, under the control of the church, over the hospitals and other charitable institutions, which were multiplying in response to the spirit of the time. With these communities begins the history of the religious nursing orders whose work among the sick presents a shining record of heroic and devoted service, covering a period of over a thousand years. Among the more famous orders, the Franciscans (*q.v.*), the Augustinians, and the Benedictines (*q.v.*) have been especially noted for their work among the sick. For twelve hundred years the Augustinian Sisters formed the nursing staff of the Hotel Dieu in Paris, and from this ancient order came the hospital sisters who in 1639 crossed the Atlantic to establish in Canada a place where the sick could be cared for.

There were many other nursing orders not all truly monastic in type. The Crusades early in the Middle Ages brought into being the illustrious military nursing orders, and the Knights Hospitallers became famous for their splendid system of hospitals, an interesting example of which is found in the old hospital of St. John at Valetta. Other nursing orders were the free secular associations, of which the Beguines of Belgium formed the most interesting example. They showed an effort away from the rigid formalism of the monastery toward spontaneous self-expression in work and life. Their little houses clustered around the hospital and nursing was their important activity. One of the most famous and the largest of all nursing orders is that of the Sisters of Charity, founded by St. Vincent de Paul in 1634. Recent data showed this order established in twenty-four countries, and working, either serving or directing, in about 2000 hospitals and other institutions. The sisters have an

honorable record of service in epidemics, war, and other disasters, and several have been decorated by France with the Legion d'Honneur. Altogether, the records of the religious nursing orders are among the most splendid pages in history and their contributions to human welfare among the most valuable.

The suppression of the monasteries was followed by a time of great hardship for the sick poor. No new system was available to replace that of the religious orders, the sick were more and more relegated to the care of servants and attendants, the art of nursing was neglected, the status of the nurse became extremely low. Writers agree that in all matters relating to hospitals and the care of the sick a period of stagnation set in during the latter part of the seventeenth century, lasting until the early part of the nineteenth. The condition of nursing during the eighteenth century is clearly shown in John Howard's reports of hospitals and lazarettos, and the typical nurse of the early nineteenth century has been immortalized by Dickens in *Martin Chuzzlewit*. The servant nurses of this period show nursing brought down to a state of marked degradation. They had become free from any control or supervision of women, and were everywhere almost entirely subject to male officials. They were ignorant and untaught, overworked and underpaid, ill-housed, ill-fed, and held in contempt. No elevating or enlightening influences reached them. Where the religious orders had seen in their work among the sick a direct and living service to God, these persons saw only disagreeable, laborious tasks, illumined neither by religious zeal nor by scientific knowledge. Nursing became simple, hopeless drudgery.

Nineteenth Century Reforms: Kaiserwerth.

— While the actual reform in nursing began with the founding of the School for Deaconesses at Kaiserwerth on the Rhine, there were various factors and influences leading up to it. The continued existence of small groups or communities of women selected to work among the sick poor, usually in connection with the church, often consecrated with religious ceremonies, showed that the order of deaconesses had never wholly died out. The form only had changed. The spirit and service remained, and these groups of workers among the sick and poor were virtually deaconesses. The hope of reviving the ancient churchly order was frequently expressed by some of the clergy during the eighteenth century, and pamphlets were written urging it. Groups of such workers were seen by Pastor Pliedner, the founder of the Kaiserwerth Schools, among the Moravians and Mennonites in Holland, and the profound impression they made on him had doubtless a direct influence in the formation of his plans.

During the latter part of the eighteenth and early in the nineteenth centuries there

were interesting attempts at formulating instruction in nursing. A number of small nursing manuals appeared, and in several places courses of instruction for hospital attendants were offered. The more noteworthy manuals were those of Dr. May (*Unterricht für Krankenschwäger, Mannheim, 1784*) and Dr. Pfahler (*Unterricht für Personen welche Kranke warten, 1793*), in which principles of nursing as well as details were discussed. These were widely read at the time, and may be looked upon as important early contributions on this subject.

Courses of instruction for male nurses were established in Magdeburg, Prussia, at the end of the eighteenth century, and institutes for hospital attendants were founded in Vienna in 1812; in Strassburg in 1814; and at the Charité Hospital, Berlin, in 1830. Writers of the day speak of the opposition to these efforts, which were apparently looked upon as a dangerous innovation. The courses offered usually covered two or three months, and consisted solely of lectures by physicians. There could, of course, be no practical teaching without nurses to teach their practice, and thus only the principles of nursing, but not nursing itself, could be taught. A certificate was given at the School for Attendants in Berlin, and, as there was an old Prussian law relating to these, here may perhaps be found the earliest example of the recognition of a legal status for nurses. A stimulus more direct perhaps than any of these, was the wonderful activity of the women of Germany in hospitals and among the sick during the War of Freedom. A plea for a definite revival of the diaconate, which would provide Christian women to do Christian nursing, was made by Fliedner, who points to the work of these women in projecting his plans for the Training School for Deaconesses, which was later established at Kaiserwerth and jointly directed and developed by himself and his noble wife Fredericke. The importance and significance of this revival of the evangelical order of deaconesses can only be fully understood by careful study of the movement and the time. The plan of training embraced many activities, but so far as nursing is concerned the whole development of the modern system may be traced directly through its founder, Florence Nightingale, to this school where she first went to study nursing methods.

The fundamental principles upon which the system of training in nursing was based were that the hospital and other institutions existed only to provide suitable places for training the pupils; that systematic and continuous instruction was indispensable; that nurses could not be narrow specialists, and must be thoroughly prepared in every phase of their work. For this purpose some time must be passed in each department to insure familiarity with all; and most important of all

was the large authority given to the woman at the head, the matron who was made responsible for the entire arrangement of work, its control and direction, and the discipline of the pupils, — the restoration of an office which had long been extinct in the civil hospitals of the time. The general plan and system of work was substantially that of the modern training school, so closely have the lines then laid down been followed. The candidate was required to bring letters from clergyman and physician. There was a period of probation to test the personal and moral qualities, as well as the mental and physical. There was a preparatory department; the pupil was under no expense for living or tuition, and received a small allowance. The work was graded, and so were the workers, through several ranks. The chain of responsibility was unbroken from probationer to superintendent.

Nursing training was given in the hospital, where the pupil was to be taught the care of acute, chronic, and special cases, and parish or visiting nursing among the poor, thus following in the footsteps of the older religious orders. A large place was given to religious work, and nursing was but one branch of the training of deaconesses. The organization shows strikingly the combined influences of ecclesiastical and military ideals. The title of Sister (which still exists in many European and all English hospitals to-day), the time devoted to religious exercises and teaching, the insistence upon self-sacrifice as a part of a nurse's armamentarium came down from the religious nursing orders. The sharply defined organization for the fixing of responsibility, deference to superiority in rank, unquestioning obedience to command, precision of orders, forms, reports, and records, all bespeak military traditions. But the introduction of a system of training and teaching, the humane attitude towards patients as individuals, the respect for labor, the comparative freedom of opinion and action which were developed at Kaiserwerth were all new. The deaconess was not a nun under another garb. She represented a new idea, — that education and training for work were essential. Kaiserwerth, in fact, with its system of theory and practice, may perhaps be looked upon as an early instance of an attempt at genuine vocational education, and as such would justly claim to have set in motion far-reaching and permanent influences.

The Kaiserwerth deaconesses now number many thousands. They have branch houses all over Germany and in foreign countries; have under their care numerous convalescent hospitals, orphanages, infant schools, special schools for blind, deaf and dumb, though the educational system and ideals of the Fliedners have not been generally maintained. The life and work of the deaconess have come more and

more closely under clerical control; and restrictions, economic on the one hand, and intellectual and social on the other, have placed her out of the stream of nursing progress. In parish and mission work, however, she is still an important and beneficent factor.

From Kaiserwerth came the impetus which resulted in the first effort in England to give practical training to nurses. Mrs. Elizabeth Fry visited Kaiserwerth in 1840, and was so deeply impressed with its system and methods that on her return she brought about the establishment in London of an Institute for Nursing which was connected for practical purposes with Guy's Hospital. In 1848 St. John's House, an Anglican Nursing Order, and connected with Kings College Hospital, was founded in London. The preliminary plans call it, "a collegiate institution" to prepare for work among the sick. Several writers, physicians and others discussed in the periodicals and press of the early nineteenth century the education of women for the care of the sick, and Southey contributed in his *Colloquies in Society* an interesting and suggestive presentation of the subject as it then appeared. Plans, projects, and actual effort had, however, one distinctive feature. They provided a religious or semireligious order of workers, and reproduced with more or less fidelity the forms of the past.

The Work of Florence Nightingale. — The creation of a new order, the establishment of new principles, and the founding of a system to develop and perpetuate them was the work of a famous English woman, Florence Nightingale. While Miss Nightingale is best known throughout the world for her remarkable work in army nursing and sanitary reform during the Crimean war, her greatest contribution to human welfare must ever lie in the system of education in nursing which she originated, established, and virtually endowed at St. Thomas's Hospital, London, in 1860. Miss Nightingale (born in 1820) came of a family of wealth, social position, and public spirit. She was highly and thoroughly educated in mathematics, natural science, classics, and languages, and had traveled extensively. She was by nature a student and an investigator. Careful mental training and discipline placed her in a position to work effectively, and her natural interest in the sick, which was displayed at an early age, led her to that prolonged and searching study upon which her brilliant achievements in sanitary and hospital reform rest. She sought every available opportunity for personal observation and study of the sick for practical experience, was twice at Kaiserwerth in training, and devoted years to a careful and exhaustive study of hospitals, organization, and nursing methods in every European country. In the awful crises of the Crimean war, the English government turned to her as the one person

qualified not only by special genius, but by special and severe preparation, to handle the colossal problems of sickness and suffering in the army, and to render the great services which her country needed. Her experiences and observations there are embodied in invaluable works on sanitary reform in the army, but the vital and permanent results of her work were the removal of old conceptions of nursing as a charity, a self-sacrificing labor for others, a meritorious act leading to heavenly reward, or a penance; and the recognition of nursing as a part of sanitary science, and of pity and palliation as unacceptable substitutes for prevention. Miss Nightingale's own view of nursing should be presented. "Nursing is putting us in the best possible condition for Nature to restore or to preserve health, to prevent or to cure disease or injury . . . to enable Nature to set up her restorative processes; to expel the intruder disturbing her rules of health and life. . . . Partly, perhaps mainly, upon nursing must depend whether Nature succeeds or fails in her attempt to cure sickness. Nursing is therefore to help the patient to live. Nursing is an art, and an art requiring an organized practical and scientific training. For nursing is the skilled servant of medicine, surgery, and hygiene."

The Nightingale School, founded by the contributions of a grateful British public to Miss Nightingale, was established on the following basis. It was secular and nonsectarian. It had a close, organic relation to a hospital of high standing with adequate facilities for teaching and experience. All practical work was based on careful teaching. Hospital officers in medical and nursing departments were specially paid for teaching; the head nurses for practical teaching, the medical men for lecturing, the matron for organizing and directing the work of the pupils. The school in its educational functions was independent of the hospital, though the students were subordinate to hospital régime, in so far as work was concerned. The theoretical teaching was by means of lectures, prescribed reading, and written reports. The actual instruction in the beginning covered but one year. It was the idea of the school to prepare women to carry this system of organization and training out into other hospitals and infirmaries, to become, as it were, pioneers and reformers, and this plan has been faithfully carried out. Preparation for private nursing was not included in the original plan, but nursing in the homes of the poor was definitely provided for. The Nightingale system, as it was called, spread quickly into the hospitals of the United Kingdom, and later found its way into various European countries. The introduction into the hospitals of a body of refined and educated women as workers and students brought about in them a striking transformation, a "moral renovation" as

one writer called it. The lessening of the mortality rate, the rapid advance of educational and scientific work and experiment in medicine and surgery, the rising confidence of the public, are unquestionably due largely to the coöperation with the physician of the scientifically educated modern nurse.

American Advance.—In America the first attempt to provide instruction for hospital attendants was made by Dr. Valentine Scamman, a medical officer of the New York Hospital, who in 1789 established there a course of lectures in connection with the Maternity Department. Other efforts were made by the Society of Friends in Philadelphia in 1839, and by the Woman's Hospital in 1861, while in 1862 the Hospital for Women and Children in Roxbury, Mass., opened a school offering a year of practice and training in the hospital with a course of lectures from physicians, to which outsiders were admitted. This school is still in existence and has done good work.

In 1873 three important training schools were established in this country, all influenced directly or indirectly by Miss Nightingale's teaching and system. These were the schools connected with Bellevue Hospital, New York, the Connecticut Training School, New Haven, and the Massachusetts General Hospital at Boston. They were established by committees or bodies, usually of women, who undertook to provide suitable quarters for a group of students, and to pay for theoretical instruction, seeking only opportunity for practical instruction and training in the hospital. In each instance, as in the establishment of the Nightingale School, there was some opposition from medical men, who, whether satisfied or not with the existing conditions, were unwilling to accept the idea of educated women assisting them in the care and treatment of the sick. The students paid nothing for instruction or for living expenses, the school supplying one and the hospital the other in return for services rendered. Usually also the hospital paid a small allowance monthly to the students, designed to meet the expenses of uniforms, textbooks, etc. The training covered one year and the students were sent out into families during the second year, ostensibly for practice and experience in private nursing, but in reality to bring in, through payment for their services, additional funds for the maintenance of the school or hospital. At the end of two years of successful work a certificate was given.

The effect of the training school upon the hospital was as markedly beneficial in this country as in England, and shortly hospitals grasped the economic significance of the system, and began to establish schools of their own.

Medicine and surgery were making rapid progress and bringing about a great expansion in hospital buildings and work. Public charity

and philanthropy was expressing itself in more and better hospital facilities, and more and more were these institutions leaning upon the training school. The rapid growth in training schools during the last three decades is shown in the statistics of the Bureau of Education for 1911. These show: in 1880, 15 schools; in 1890, 35 schools. Statistics secured by Mr. Sutton and published in his *Hospital and Training School Directory* in 1910 show over 1300 training schools in this country at that date. There are said to be about 30,000 students in the training schools of the country at this date (1913).

These schools are almost universally owned and managed by hospitals, whether these institutions are state, municipal, endowed, or private and special corporations. The responsibility of the school is readily assumed by hospital authorities for the following direct and definite reasons, and others more or less subtle and indirect. first, the obvious economy of carrying on a large, essential, and highly important department through a staff of student workers; second, the fact that through such a body under a proper system of organization, instruction, and supervision an efficient and stable system of nursing is insured; third, the ease, if educational standards are not rigidly enforced, of securing a sufficient number of student workers; fourth, the intangible but valuable asset of the spirit prevailing in an institution where the workers are all seekers after knowledge and skill. Under this system the school has become to all intents the entire working staff of the hospital, economic and other considerations pushing its members, while still students, upward into the responsibilities of official positions and downward into the performance of unskilled domestic duties. The need in all hospitals for continuous twenty-four hour service, the constant improvement in methods and elaboration of details, the very nature of the work, all have called for a comparatively large staff of workers; but hospital limitations in resources have kept the numbers of the students restricted. The hours of work consequently have been long, and students thus unable to profit fully even by such limited theoretical instruction as has been offered. Such conditions have made the development of a sound and progressive educational system extremely difficult, yet progress has been made, and many radical changes have been introduced during the last fifteen years. The course of instruction has advanced from two years to three; there has been marked improvement in actual teaching, in character, extent, methods; new subjects have been introduced and old subjects more thoroughly taught; clinical teaching and supervision of students' work in wards is vastly better than it was even ten years ago. Libraries, teaching facilities, are appearing, and during the last five years a demand for trained

teachers has arisen. About ten years ago preparatory courses were introduced into a few leading training schools, with the intent of giving the students the larger part of their groundwork in science before permitting them to begin practical work in the hospital. These courses have proved valuable, and are now established in eighty-six schools, chiefly the leading schools in the country. The time devoted to this scientific instruction is six months in some schools, but ordinarily does not exceed three months, in which the student will perhaps receive all the instruction in fundamental sciences of anatomy, physiology, bacteriology, chemistry, which the school can give her. It is a movement in the right direction, but a longer period should be encouraged. There are promising indications of progress in a few schools which have established relationships with universities or colleges, thus securing there the required scientific groundwork for their students. Typical instances of this affiliation may be found in the Northwestern University, Chicago, which provides teaching in fundamental sciences for three training schools, and in Simmons College, which has for years been affiliated with certain Boston training schools. There are also a few training schools having direct connection with universities through the medical schools of which they form a sort of sub-department. Advantages of many kinds arise from this connection, and as there are now fourteen schools related to universities on some such basis, there is good reason for assuming that extensions in this direction may be looked for. The training school recently established in the University of Minnesota is an interesting and important instance of this tendency. Much of such educational progress as has been made is due to the efforts of a few leading women in the profession. The most noted and able of these was Isabel Hampton Robb, the first superintendent of nurses and principal of the Training School connected with the Johns Hopkins Hospital, Baltimore, — a woman of exceptional power, initiative, and organizing ability. Under her régime many important advances were made in nursing.

There are aspects of the work, however, in which little progress has been made. The hours of practical work still remain excessively long. In nearly 50 per cent of all schools the students still work ten hours daily, and twelve hours at night. The eight-hour day established in some hospitals many years ago has not made great headway, and a full eight-hour system is found only in four schools in the country, though sixty-nine in all have introduced a partial system which provides eight hours by day, and ten or twelve by night. It is of course manifestly impossible to develop any sound system of instruction until the hours of practical work can be greatly reduced, and

from the standpoint of the patients, of stability in hospital service, of expense, this will be difficult to accomplish. In all schools the time devoted to theory is meager, the maximum time throughout the three years not exceeding three hours weekly. Emphasis is, at all times, laid strongly upon the practical, and the true relation of theory to practice, of thought to action, is but dimly apprehended.

Professional Associations. — Educational progress has been greatly stimulated by and indeed it may almost be said to date from the organization of nurses into alumnae associations, state and national. The Society of Superintendents of Training Schools for Nurses formed in 1893 has rendered steady and valuable services in the improvement of hospital and training school work. Through its efforts courses were established at Teachers College in 1899 to prepare graduate nurses for supervision and teaching in training schools. Recently this has been developed by endowment into a department in which the original plan has been carried further, and preparation offered in sanitary and social science for public health workers. This society also brought into existence the Associated Alumnae of Training Schools which has recently become the American Nurses' Association. Both have been vigorous and active in securing legislation, in supporting professional journals, in urging forward and strengthening good educational and professional standards, training, and ideals. In any criticism of the weakness of the modern training school, the strong features of its work must not be overlooked or minimized. The student's actual theoretical teaching may seem weak, but the lecture and classroom have a comparatively small place in her training. Clinical bedside instruction, daily work under the constant supervision and criticism of expert workers, rich opportunities for study and observation, close daily association in work with medical and surgical experts and specialists, are the main and most important educational factors.

The Present Situation. — Beyond this the moral and ethical demands upon the student, inherent in the very nature of her work, are such as to form an educational influence of a very high order, and to develop a personal discipline and a sense of responsibility of distinct social value. The work of nursing is rooted deeply in vital human needs. It has, and has always had, an extraordinary appeal to many women. For years, while few occupations besides teaching and nursing were open to women, there were a great many applicants to training schools. The early schools attracted many women of excellent education, much ability, altruistic leanings, courage, spirit, and devotion. The opening up of many new opportunities for women has drawn from the large number of candidates formerly available, and the long hours of work, meager edu-

cational advantages, and other conditions have made nursing, or rather the training process, seem unattractive to the ordinary intelligent women of the day. There is now serious difficulty in securing enough students to maintain the system without so lowering or disregarding educational standards, as to imperil the welfare of the sick and the status of the profession. Those schools offering the best and soundest educational work, shorter hours for students and good living conditions, attract a reasonable number of satisfactory candidates. But no school can be assured of a student body of desirable caliber large enough to staff the entire hospital. The moment hospital requirements become the main or ruling factor in the selection and admission of students, standards of education or of personal fitness cannot be maintained, and standards and character of work in both school and hospital must eventually deteriorate.

Two forces are now at work which are beginning to influence training schools appreciably. The first is found in the legislation, providing for state registration of nurses, which has now been secured in thirty-four states, largely by associations of nurses. While most of these laws are permissive only (but seven are mandatory), they have set up definite, if moderate, educational and other standards, and have accomplished genuine improvements in hospital and training school work.

The other factor affecting educational methods is the passing of the nurse from the actual care of the sick in hospitals, and homes, over into the field of public health work. Preventive work for the protection of infant life, of the health of the school child, of the health of the young industrial worker in factory or shop, and in relation to tuberculosis, is largely relegated to the nurse as the logical person to apply directly the teachings of sanitary and medical science. Health nursing of which Florence Nightingale wrote nearly half a century ago is now beginning to take shape, and as educational propaganda form an essential factor in such work the nurse must be so educated and trained as to be able to meet this new requirement. There are nearly a thousand associations, large and small, in which nurses are engaged in public health work.

A new and important demand is made upon the hospital training school which must eventually be met either by it or by other institutions of another type. Already such efforts are projected. Since, however, there are already the elements of a practically perfect system existing in the modern hospital and training school, it would seem better to make such changes in the relationship between them, such reshaping and reconstruction, as will provide autonomy for the training school. Such changes, partly governmental, partly economic, would enable the school to fulfill

adequately its essential functions, and to serve its full purpose in the community. On any other basis than this it is almost certain to degenerate.

Other Countries. — The general situation as regards nursing in other countries may be briefly summed up as follows:—

In Australia the nursing profession is highly organized, and works in close cooperation with medical men. Educational and professional questions are prominent and given first importance. A system of voluntary minimum requirement and examination has been universal and effective because state subsidies of hospitals enable governments to make conditions, and the National Association of Nurses, in which doctors are included, has been able to get government endorsement of standards. The minimum is three years in general work, — special studies and special examinations for intending superintendents of hospitals and training schools. State registration and examination has just, during the current year, become law in Queensland. Very similar conditions exist concerning nurses in New Zealand, except that it has had state registration and examination under national law since 1901, with excellent results. The course of training covers three years.

In Japan, training for nurses under the Red Cross is highly perfected. The training of nurses is, however, carried on under a paternal system and nurses have little voice or direction in the development of their own standards. Patriotism and self-sacrifice are the leading motives among Japanese nurses, but they are also very markedly efficient in details of practical work. The course covers three years. City hospitals have training schools but not of the same standards as the Red Cross.

In India there is a vast movement to obtain a minimum of practical and theoretical work in training native women. At present there are great variations and very little uniformity in efforts. Mission schools exist with a very weak and inadequate curriculum. A few hospitals are established on the best English models. Complications of language add to the difficulties of the work, but associations of superintendents and alumnae, made up, however, almost entirely of English and American nurses, are at work upon the nursing problem.

In China an excellent attempt at hospital and training school work has been recently initiated under the auspices of the Chinese government with a medical woman in charge of the hospital and an English trained nurse as head of the school.

In Italy pioneer work has been done for some years in Naples, Florence, and Rome by English and American nurses. Their work has brought about modern training schools in connection with several hospitals, more recently the Policlinico in Rome under the pro-

tection of Queen Helen. This has a modern system and a three years' course, and has a promising future.

In France there has for some years been a state of unrest in hospital and nursing fields, owing to the secular strife which removed nuns from hospitals under government control and brought about a crude process of laicisation, largely with untrained women. The Nightingale system of nursing was introduced into two Bordeaux hospitals by Dr. Anna Hamilton, and an admirable and thorough educational system has been established. The French government is now entirely committed to the principle of education for nurses and a new school of nursing was established under the city administration in Paris in 1907, in connection with the Salpêtrière and on a sound educational basis.

In Germany the general high state of cultivation by the government of technical and advanced education has not been extended to nursing, the reason perhaps being that it was long left to religious bodies to perform as unpaid labor of self-sacrifice and humble devotion. German nurses are now demanding three years of training and systematic teaching. The government has enacted permissive state examinations and registration with a minimum term of one year of training. A strong organization of nurses in Germany has given strength to the nursing movement, and it is seeking alliance with the woman's movement to demand higher conditions of labor and better instruction.

In Belgium a very elementary state registration act has been in force for several years. The early stage of transition from nursing by religious orders to the modern system is clearly seen here. Brussels city administration has founded a training school on the plan of the Paris school.

In Holland there appears to be complete indifference to the educational demands of nurses on the part of state authorities and a striking contrast is here shown to the desire of the French government to educate. Holland public men are satisfied with public school grade (at twelve years) for nurses, and the outlook for better standards is small at present.

In Scandinavian countries there is a general three years' course which is not well balanced. Educational requirements for pupils are generally high and the training excellent, although a number of subjects must be taken as specialties, thus making five or six years of study and training necessary.

In Great Britain, notwithstanding the fact that the modern system of training was developed in England, that district nursing and school nursing both originated there, it has been impossible up to the present to establish definite standards of education and registration for nurses. Every hospital is a law unto itself. Hospital directors resist the movement

for registration urged by nurses, and show a general public unwillingness to regard nursing as an educational question. Three years' training is general. There is little theory, but high standards of practical work. From the very beginning many women of especially high educational and personal qualities have been drawn into nursing ranks. The movement for legislation concerning nurses and registration has been on foot in England since 1888. M. A. N.

NUTRITION. — See FOOD AND FEEDING OF SCHOOL CHILDREN.

NYPHOMANIA. — Abnormally great and uncontrollable desire for sexual excitement and gratification. The term is applied to woman, and the term satyriasis to man. Both differ from erotomania in that the latter is largely mental, the physical gratification being mainly replaced by ideas of love and of sexual matters in modified forms. These conditions are often found in children, especially in the feeble-minded. S. I. F.

See SEXUAL ANOMALIES.

OAKES, URIAH (1632-1681). — Fourth president of Harvard College; was graduated from Harvard in 1649. While a student at Cambridge he invented a set of astronomical calculations. After graduation he went to England and was pastor at Titchfield in Hampshire. He was silenced "with the other nonconforming ministers" and returned to America and was president of Harvard College from 1675 to 1681. In the opinion of Dr. Mather, America never had "a greater master of the true, pure Ciceronian Latin."

OATHS OF TEACHERS. — See NEVADA.

OBERLIN COLLEGE, OBERLIN, O. — A coeducational institution founded in 1833 by two home missionaries, natives of Vermont, Reverend John J. Shipperd and Mr. Philo P. Stewart, and named after the devoted and far-sighted Alsatian pastor and philanthropist, Jean Frederic Oberlin (*q. v.*). The founders hoped to establish a community and educational center that might do in the Mississippi Valley work something like that accomplished by Oberlin in Steintal. There was no definite attempt to be revolutionary, except in the Christian standards of the community established. But in the outcome, the institution did prove a pioneer in various directions. Full college education was opened to women, college coeducation of the sexes adopted, race barriers thrown down in the decision of the trustees in 1835 to admit students "irrespective of color," and the community became a center of anti-slavery and missionary agitation. Work in the preparatory department of the College began in 1833, and in the College department in 1834. The theological department was instituted in 1835, under the leadership of Reverend Charles G. Finney, the theologian and evangelist. The early teachers were largely from New England, and the college standards adopted from the first were those of the best New England colleges. Four young women were enrolled as freshmen in the regular college course in 1837; three of these were graduated in August, 1841, and are supposed to have been the first women to receive degrees in the Arts under the standards prevailing in the best men's colleges of the day. The Oberlin Conservatory of Music was organized as a department of the college in 1867. The College now regularly gives the degrees of A.B., Mus. B., A.M., and B.D. The entrance requirements for admission to the College of Arts and Sciences are fifteen units. The same requirements are now made for admission to the Conservatory of Music. Candidates for the degree of B.D. in the Theological Seminary must have the rank of college graduates. Oberlin is on the original list of accepted colleges of the Carnegie Foundation for the Advancement of Teaching.

The College has always had a self-perpetuating Board of Trustees, without denominational tests of any kind. Since 1890 the Alumni have elected one fourth of the Board by direct vote. There are at present seventy-five professors and associate professors, and sixty-eight other teachers and officers. For the year 1911-1912, there were enrolled in all departments 1780 students (all but 300 of college rank, and 998 in the College Department itself) from forty-five states and sixteen foreign countries; more than one half from outside Ohio. The alumni list numbers 6691; and the total number of students who have studied in Oberlin College since 1833 is 38,133. The college library contains 120,000 bound volumes, and about the same number of unbound volumes and pamphlets. The productive endowment of the college (March 1, 1912), is \$2,207,046.32, and the value of buildings (twenty-two), grounds, and equipment, is \$1,634,338.14. The total assets of the college amount to more than \$4,000,000. The entire annual income of the institution from endowment and term bills for the year 1910-1911 was \$386,735.50.

OBERLIN, JEAN FREDERIC (1740-1826). — Philanthropist and educator, was for nearly sixty years pastor of the Ban de la Roche (Steintal), a big and sterile district, some thirty miles southwest of Strassburg. His heroic and successful efforts to civilize a people suffering from the ravages of war and lapsing towards barbarism attracted the attention of Europe. He had roads constructed and better houses built; he taught improved methods of farming and introduced fresh industries; but his most fruitful work was the education of the young and his most novel device the establishment of infant schools. These were directed by motherly women, one of whom, Louise Schepler, was awarded a Monthyon *grand prix de vertu* and is described on her tombstone as "*fidèle servante et collaboratrice de Papa Oberlin . . . conductrice de la jeunesse.*" The aims of the infant schools were rooting out bad and forming good habits; inculcating the first notions of morality and religion; teaching the elements of reading, writing, and arithmetic; and eliminating the use of patois. The little ones were assembled in spacious rooms. The youngest played together while the rest were learning to spin, to knit, and to sew. Natural history and scripture were taught by pictures. In fine weather the *conductrices* took their charges for walks and made them find the flowers which had been described to them. These became the subjects of familiar talks and a desire to grow them was created.

In 1801 Mme. de Pastoret, inspired by Oberlin's example, established in Paris a *salle d'hospitalité*, but it was more a crèche

than an infant school and does not appear to have lasted very long. D. S-N.

OBERREALSCHULE.—The upper scientific school in the Secondary School System of Germany

See GERMANY, EDUCATION IN.

OBJECT AND SUBJECT—The older classic use of the terms subject and object was the opposite of that current to-day. According to the Aristotelian logic only substances, things existing as individuals not as qualities or properties of things, could be subjects of propositions and the subject matter of adequate knowledge. Subject and substance were thus practically identified; some trace of this meaning remains in the current use of the term subject matter. Scholastic philosophy, under the influence of Arabian thought, introduced the term "object" to designate things in their "second intention," that is, not as things on their own account, but as objects of thought or mental consideration. A chimera would thus exist objectively but not as a subject, according to the opponents of Platonic realism, universals (man, as distinguished from individual men) also had existence only objectively. Modern philosophy effected a complete reversal of this usage. The tendency began with the introduction of the psychological mode of thinking of Locke and his successors, and was practically completed by Kant. As the function of the self as the center of thinking, feeling, knowing, was insisted upon, the term subject was more and more used as a synonym for ego, mind, self, and the adjective subjective to denote mental existences. The problem of the relation of subject and object came to mean the problem of relation of mind and the world, especially as they enter into the constitution of knowledge. By the transcendental idealistic school much was made of the fact that the thinking ego is at once subject-object, since the thinking self is capable of presenting itself to itself as object. In self-consciousness, as thus defined, was found the key to the problem of the relation of particular minds or sentient subjects to the world,—a conception that had a great vogue in post-Kantian idealism. J. D.

See EPISTEMOLOGY; METHOD; SELF.

OBJECT TEACHING.—Object teaching was not, as the term may seem to imply, a mere method of imparting knowledge through the means of objects themselves, but a complete scheme of elementary instruction. It may be said to be an application of the inductive method to the teaching of children. Its aim was to begin with the training of the senses and proceed from this to the development of the entire nature of the child. The chief laws of its method were. (1) instruction by actual inspection; (2) go from the easy to the difficult; (3) give in each hour, if possible, a little whole in contents and form; (4) use conversation. All the great thinkers and educators from Luther on, Rabelais, Francis Bacon, Comenius, Locke, Rousseau, and the rest, forecast the principles which were developed by subsequent effort into object teaching.

Comenius (1592-1670) was probably the first definitely to formulate the principles of object teaching and to work out a graduated system of instruction applying the inductive method to schoolroom procedure. "Since the beginning of knowledge must be with the senses," he says, "the beginning of teaching should be made by dealing with actual things. The object must be a real, useful thing, capable of making an impression upon the senses. To this end it must be brought into communication with them: if visible, with the eyes; if audible, with the ears; if tangible, with the touch, if odoriferous, with the nose; if sapid, with the taste. First the presentation of the thing itself, and the real intuition of it, then the real explanation for the further elucidation of it" (*The Great Didactic*, Ch. XX, §5-7). But inasmuch as the presentation of the thing itself is so frequently impossible, he advised the use of pictures as the representations of things, that the words which related to them might be understood. He prepared and published textbooks, putting his theories into practice. These books were translated into various languages and were used for many generations wherever there were schools for children. The best known of these is the *Orbis Pictus*, or the *World in Pictures*. (See COMENIUS.)

After Comenius, Rousseau (1712-1778) is worthy of special mention as having been the first to base his educational theories on the child to be educated. The child's experience, accordingly, the facts of nature round about him, is to furnish the material for education. "In general, never substitute the sign for the thing itself, save when it is impossible to show the thing; for the sign absorbs the attention of the child and makes him forget the thing represented." (*Emile*, Book III.) It was as a result of acquaintance with *Emile* that Pestalozzi first conceived the idea which he subsequently expanded into the system of which he is worthily entitled to be called the father. (See ROUSSEAU.)

Pestalozzi (1746-1826) did the most, not only to formulate object teaching, but also to put it on a scientific, philosophic basis. "The most essential point from which I start is this: Sense impression (ANSCHAUUNGSUNTERRICHT) of nature is the only true foundation of human instruction because it is the only true foundation of human knowledge. All that follows is the result of this sense impression and the process of abstraction from it." (*The Method*, translated by Lucy Holland and Frances Turner and edited by Ebenezer Cooke, second edition, p. 316.) "The means by which a man whose mind is cultivated makes clear to himself all knowledge gained by sense impression come from number, form, and language. The instruction of children therefore should proceed from these three elemental points: (1) to teach them to look upon every object that is brought before them as a unit,—that is, as separated from those with which it seems connected; (2) to teach them the form of every object,—that is, its size and proportions; (3) as soon as possible to make them acquainted with all the words and names descriptive of objects known to them." (*How Gertrude teaches her Children*, translated by Lucy Holland and Frances Turner and edited by Ebenezer Cooke, second edition, p. 145.) According to these principles Pestalozzi divided his object lessons into three classes: (1) those on number; (2) on form; (3) on speech. Those on number were mainly lessons in mental arithmetic; those on form comprised geometry, drawing, and writing; those on speech included instruction in speaking and singing tones, instruction in words, or the means of becoming acquainted with single objects, and instruction in language itself, or the means of expressing one's self clearly, not only upon number and form, but also upon all other qualities of things, as well those qualities which are perceived through the five senses, as those which are perceived, not by means of a single intuition of them, but by means of our faculties of imagination and judgement." Thus the lessons on speech became the basis for instruction not only in spelling, reading, and language, but in geography, history, and natural history as well. It is not within the purpose of this article to criticize. It is well known, however, that in developing these principles Pestalozzi failed to observe the order in which he first formulated them. In his books, instead of providing for beginning with the object itself and calling attention to its identity and form, he began with words about objects and not even about objects to be under observation at the time, but about objects remote and incapable of being brought within the view of the child. In his schoolroom practice his impatience impelled him continually to prompt the pupil in both the idea and the expression of it, so that he often omitted altogether the first two elemental points of in-

struction and allowed the third to degenerate into an exercise in mere words. His so-called object lessons were not object lessons in fact, and were not even lessons in language. (See PESTALOZZI.)

In Germany Pestalozzi's disciples caught the spirit of his method. Taking his philosophic principles rather than his exposition of practice of them as a basis, they adapted them to their own needs and wrought out a system of their own; whereas Pestalozzi set up the human body as the nearest and ever present object lesson to the child, they proceeded in a more natural manner and struck out the following sequence: schoolroom, family, house, house floor, the sitting room, the kitchen, the ground, the cellar, the yard, the habitation, the city, the village, the garden, the field, the meadow, the wood, the water, the atmosphere, the sky, the season, the year and its festivals, man, body and soul—God. Or again, Diesterweg (1790-1866) finds seven different kinds of intuitions to be awakened: sensuous, mathematical, moral, religious, æsthetic, purely human, and social. Others were still more independent in working out and applying the Pestalozzian theory. Early in the last half of the nineteenth century object teaching had become established in the majority of the elementary schools of Germany. This had not been accomplished without serious opposition. The famous Prussian Regulation of October 3, 1854, spoke plainly on this subject. In 1872, however, a committee appointed by the Congress of Elementary Teachers meeting in Berlin submitted to Dr. Falk, the Minister of Ecclesiastical Affairs and Education, a set of resolutions or requests among which was one recognizing the importance of object teaching and asking for the organization of training schools in accordance with the pedagogic principles of Pestalozzi. For half a century before this time the question of object teaching had been engaging the best efforts of the leading educators in Germany. Among the many books on the subject may be mentioned those of Plamann, Denzel, Harnisch, Diesterweg, and Carl Richter (*q.v.*).

In France Pestalozzi and his methods were repudiated by Napoleon and were given no countenance in the schools during his time. From the downfall of Napoleon to the Franco-Prussian War the value of the labors of Pestalozzi was recognized by the leading educators of France, and his methods were in some instances put into practice. Jullien and Chavannes both placed their children under Pestalozzi's tuition and endeavored in various ways to arouse interest in Pestalozzi's work. Maine de Biran (*q.v.*) opened a Pestalozzian school at Bergerac in 1808, which continued in existence for nearly seventy years. Object teaching was not adopted as a system in the schools of France nor put into general use in

any way prior to the Franco-Prussian War. After the close of this war a new impetus was given to the Pestalozzian movement. At the exhibition of 1878 a conference of the teachers of France considered the question of sense-impression teaching, which resulted in placing it on such a firm basis that it was generally introduced into all the elementary schools.

In England the object lesson as a separate branch of study was first given prominence. Charles Mayo (*q.v.*), who had spent almost a year in Pestalozzi's School at Yverdon, and his sister, Elizabeth Mayo, through the Home and Colonial Training School at Gray's Inn Road, London, attempted to reduce the Pestalozzian principles and methods to a practicable shape by the preparation of graduated courses of instruction. Manuals about objects and lessons on those objects to be learned and recited to the teachers were the ultimate result of the attempt of Charles Mayo "to preserve the Idea but adapt the Form" to those circumstances in which he might be placed. (See INFANT SCHOOLS; HOME AND COLONIAL INFANT SCHOOL SOCIETY.)

In America object teaching was employed in the various Pestalozzian schools of Joseph Neef (*q.v.*) in Philadelphia in 1809, in Village Green, Pa., in 1813, in Louisville, in 1816, and in New Harmony, Ind., in 1825. The Westfield Normal School (established at Barr, Mass., in 1839, removed to Westfield, Mass., in 1844) was the pioneer in introducing object teaching into the public schools. This school was also the first to show that all branches of learning may be taught by the same objective method. Object teaching at Westfield, however, attracted little general attention. It was left to the Normal School at Oswego, New York, to become the center of object teaching in America. In 1860 Edward A. Sheldon (*q.v.*) while on a visit to Toronto saw in the National (Educational) Museum there collections of the pictures, models, objects, and appliances used by the Home and Colonial School Society in England. The schools of Oswego had been developed out of his philanthropic activities; it was in the interest of these schools that he visited Toronto, and on his return to Oswego he at once began the reorganization of the schools there with special reference to object teaching. He was well fitted to make this adaptation by his previous thinking along the same lines and by his own earnest and partially successful efforts to make practical the education of the poor. In 1861 Miss M. E. M. Jones formerly connected with the Home and Colonial Training School, above referred to, came to Oswego as a training teacher and further elaborated the principles of object teaching. She was succeeded in the following year by Hermann Krüsi, Jr. (*q.v.*). The system became thoroughly established at Oswego. Mr. Sheldon and the other authorities at

Oswego stood firm against the hostility aroused by their new methods. At their invitation in 1862, a committee of the leading educators of the country investigated the nature of the new work. Subsequently, as a result of a paper read by Mr. Sheldon before the National Teachers' Association held at Chicago in 1863, that association appointed a committee to look into and report upon the principles of object teaching. This committee reported at the meeting of the association held at Harrisburg in 1865. With only one dissenting voice the report was heartily in favor of the adoption of object teaching in the elementary department of the public schools. The Oswego Normal School continued to be the center of influence for object teaching until its principles and methods became fused with those of the nature-study movement. In 1876 Professor H. H. Straight, a disciple of Agassiz and Shaler, went to Oswego. His views of science teaching in the elementary school underwent gradual but decided change under the Pestalozzian influence in which he was placed, and the object lesson of Oswego was modified in turn by Professor Straight, who recognized the need of system and correlation. William T. Harris (*q.v.*), inspired by Pestalozzian principles, worked out a method for the teaching of natural science. The study of natural science was introduced not only into all grades of the elementary schools of St. Louis, but through the direct and indirect influence of Dr. Harris, it became incorporated, in one form or another, into the curricula of most of the common schools of the United States. So that it is reasonably certain that nature study at least in spirit is the direct descendant of object teaching. It may safely be asserted that, not only in America but in all other advanced countries as well, most of the accredited methods of elementary instruction now in use, can be traced more or less directly to the principles of object teaching. E. R.

OBJECTIVE METHOD.—The use of concrete experiences, of sense perceptions, as a basis for teaching ideas, concepts, relations, etc., and for giving the meaning of language symbols, is termed an objective method of instruction. It assumes a wide variety of forms. When first introduced into the elementary classroom, it implied the bringing of objects into the classroom; later it included school excursions, where pupils leave the school-room to make observations of natural and institutional facts. Laboratory teaching is

a form of objective work. The action work employed by primary children in acting out the meaning of sentences read by them, and the more complicated children's dramatizations of literature are derived modes of objectification which aid in giving clear sense impressions. Such visual aids as pictures, graphs, and maps are likewise objective inasmuch as they are pictorial substitutes for real objects.

Prior to the second quarter of the nineteenth century there was little object teaching. The use of objects in giving a concrete basis for abstract notions seems to have gained its initial hold on the schools through the introduction of Pestalozzian methods of teaching. The introduction of school subjects requiring objective treatment, such as elementary science, nature study, and manual training, fortified the previous movement and gave it considerable extension. Together these two movements established the respectability of objective teaching. Schoolroom experience quickly gave it an empirical sanction. It remained for the modern psychological movement in education to give it a scientific sanction and to refine its uses.

It is quite fair to say that the use of objective work decreases more or less gradually from the first to the last year, the underlying assumption being that the use of objects has a teaching value that decreases as the maturity of the pupils increases. Current practice does not proceed far beyond the application of the simple and somewhat crude psychological statement that the youngest children must have much objective teaching, the older less, the oldest least of all. The lack of a more refined analysis of the worth of object teaching necessarily leads to some neglect and waste. Examples from the teaching of arithmetic, where objective teaching has been a matter of greatest controversy, will indicate the status of objective teaching in general. If a topic occurs late in the course of study, as in the case of square root, the subject is not so well taught because of the current prejudice or tradition against the use of object teaching in the higher grades. On the other hand, it is also probable that the teaching of addition is often accompanied by wasted time and energy simply because lingering over objects in the lower classes is the current fashion. Reform in the direction of a more refined and exact use of object teaching is suggested by the extended objective treatment of fractions and mensuration, which partially disregards the increased maturity of the children studying these topics. This is a considerable departure from the slight objective treatment of other arithmetical topics taught in the same grades. Such exceptional practices suggest that the novelty of a topic is the condition calling for objective work in instruction. It is immaturity in a special subject or situation which determines the amount of basal objective work required.

The correlation is not with the age of the pupil, but with his experience with the special problem or subject in hand. It is of course true that the less experienced the student is, the greater the likelihood that any subject presented will be novel and strange. Only in this indirect manner does the novelty of subject matter coincide with mere youth as an essential principle in determining the need of objective presentation. The naive assumption of the older enthusiastic reformers that objective work is a good thing psychologically, one of which the pupil cannot have too much, is by no means the accepted view of the modern educator. With the latter, objective presentation is an excellent method at a given stage of immaturity in the special topic involved, but it may be uneconomical, even an obstacle to efficiency, if pushed beyond.

There is, then, a certain coincidence of the psychologist's scientific criticism and the conservative teachers' common-sense criticism when both look suspiciously upon a highly extended object teaching. The teacher, on grounds of experience, says that too much objective teaching is confusing and delays teaching. The psychological critic says it is unnecessary and wasteful. The result is that the distribution of objective work has somewhat changed of late. More subjects are developed in the higher grades through an objective instruction than before. Perhaps no fewer subjects in the lower grades are presented objectively, but the extent of objective treatment of each of these has undergone considerable curtailment.

The existing defects in objective teaching are not restricted to a false placing or distribution. The quality of the teaching use of objects is likewise open to serious criticism. Object teaching is a device so successful, as against prior non-objective teaching, that it has come to be a standard of instruction as well as a means. As long as objects—any convenient objects—are used, the teaching is regarded as good. Given such a sanction, the inevitable result is an indiscriminating use of objects. The process of objectifying tends not to be regulated by the needs of the child's thinking life; it is determined by the enthusiasm of the teacher and the materials convenient for school use.

The first fact which is noted in estimating objective teaching is the artificiality of the materials employed. Primary children count, add, etc., with things they will never be concerned with in life. Lentils, sticks, tablets, and the like are the stock objective stuff of the schools, and to a considerable degree this will always be the case. Cheap and convenient material suitable for individual manipulation on the top of a school desk is not plentiful. But instances where better and more normal material has been used are frequent enough in the best schools to warrant the be-

lief that more could be done in this direction in the average classroom. The "playing at store," the use of actual applications of the tables of weights and measures, are cases that might be cited.

The materials used are not only more artificial than they need be, but are too restricted in range. As has already been said, the types of material capable of convenient and efficient use in a schoolroom are not numerous. But the series can and ought to be extended. More forms of even the artificial material should be used, thus minimizing the danger of monotony. The blame for the narrow range of materials used falls partly on school boards who do not vote a sufficient allowance for teaching materials to primary teachers; partly on teachers who do not exercise sufficient ingenuity in devising new forms of objects or show the vigor requisite to a shift from one material to another; and partly on the supervisory staff which has neither been insistent upon nor sensitive to the need of a more interesting range of objective stuffs.

Even the narrow range of materials in general use might be better employed than it is. There is, of course, a distinct tendency to vary the object, merely because a child gets tired of it as a material. But a different quality of variation is required when the pupil is to derive abstract notions from concrete materials. It is too frequently the case that the teacher will treat the fundamental addition combinations with one set of objects, *e.g.* lentils. In all the child's objective experience within that field there are two persistent associations — "lentils" and "the relation of addition." The accidental element is thus emphasized as frequently as the essential one, and being concrete has even a better chance to impress itself. A wide variation in the objective material used would make teaching more effective, particularly with young children.

The nature of the materials proper to objective teaching has likewise been too narrowly interpreted. Objective teaching has meant, almost exclusively, instructing or developing through three-dimensional presentations. There is a wide range of two-dimensional representations, *i.e.* pictures, which have been neglected, which for all the psychological purposes of education have as much worth as so-called objects. Such quasi-objective material has been little used by teachers save as it appears in textbooks. Even the textbook writers have not used pictures with a deep sense of their intrinsic worth. They are printed as a mere substitute for objects in a period when objects are popular pedagogical materials. The geometric figure or diagram has had a restricted use with both the teacher and the textbook writer. Its most frequent use has been in treatments of mensuration. There are, of course, obvious disadvantages to pictures and diagrams. The things repre-

sented in them and by them are not capable of personal manipulation by the child in the ordinary sense. But they have a superiority all their own. They offer a wider, more natural, and more interesting range of concrete experience.

There are other curious phases of narrowness in the current pedagogical interpretation as to what constitutes a concrete or objective experience. It will be noted that visual objects are the ones generally employed and that they are generally inanimate objects. Of late there has been some tendency to use hearing and touch as a concrete basis to teaching. Advantage is also taken of the social plays of children, and their games with things. Here the children themselves, and their relations and acts, are the experiences from which abstract notions are obtained. With some of the best teachers in the lowest grades it is no longer unusual to see children moving about in all sorts of play designed to add reality to, and increase interest in, language and its concepts.

The conservative teacher's use of objects is artificial and lacking in unity. If he brings a series of objects into the development of a single topic, they have little relation to each other. They represent no actual grouping. Their sole connection with one another is that they exemplify the same abstract truth. Beans, cardboard squares, and shoe-pegs may all be employed in the same lesson. The progressive teacher offers more logical unity in their materials. To "play at store," to utilize games, to deal with things within a single picture, is to bring the concrete materials into the classroom with a more nearly normal setting. It is in no small measure due to this better use of material that the progressive teacher is gaining power throughout the elementary grades.

Inductive teaching has been one of several movements affecting objective teaching. The effort of teachers to escape the slavishness of mere memoriter methods and to approximate real thinking led to the introduction of inductive teaching. Necessarily objective teaching became more or less identified with the new movement and was influenced by it. So, it has been said of objective work in arithmetic, as it has been said of laboratory work in the sciences, that such instruction is a method of "discovery" or "rediscovery." Such an alliance has had its beneficial effects upon objective teaching; it has redeemed it from the aimless "observational work" of an earlier "objective study." But too frequently it confused an objective mode of presentation with a scientific method of learning truth, two activities having a common logical basis, but not at all the same. Under the assumption that the "development" method is one of "rediscovery," the tendency is to give the child as complete a range of concrete evidences as would be necessary on the part of the sci-

tist in substantiating a new fact. The result is that long after the child is convinced of a truth the teacher persists in giving further objective illustrations of it. The child loses interest in the somewhat monotonous continuance of objective manipulations, and the teacher has naturally wasted time and energy. If the fact or the process that the teacher wishes to convey can be transmitted with fewer objective treatments (the authoritative treatment of the teacher counting for something in school as authority counts everywhere), then it is unnecessary to exhaust the objective treatments of a fact. Inductive teaching and learning are not equivalent to inductive discovery; and to hold them identical is necessarily the too great use of objects in teaching.

Another modern movement in teaching method which has had a conspicuous effect on objective teaching is the movement toward "self-activity" on the part of the child. The recent favor enjoyed by manual training, nature study, self-government, and other active phases of school life is an index of the general movement in mind. Its influence has not only forced the introduction of new subjects; it has changed the manner of presenting the older subjects of the elementary curriculum. Reading, language, spelling, and arithmetic have responded by incorporating an active use of objects by the children themselves. There was a time when objective work in the schools was a passive matter so far as the child was concerned. Any active manipulation of the objects that might be required was cared for by the teacher, the child being merely a passive observer. This is at present much less the case than formerly, the influence of "self-activity" having entered into contemporaneous pedagogy. The present situation is one where the child sometimes merely observes objects and sometimes actually handles them. At one extreme the teacher himself demonstrates in the presence of the class, and records the relations in appropriate symbols, the class being in the position of interested spectators of a process. At the other extreme the teacher puts the objective materials on the desks of the children and, with a minimum of instruction in advance, directs them towards the desired experiences and conclusions.

There is probably no single type of method which has been as influential for good in the schools as objective teaching. But the appropriate refined use of the varied forms requires an analysis and care which the average classroom practitioner has not given. More accurate interpretations and applications of the method are necessary.

OBLATES OF MARY IMMACULATE, THE. — See TEACHING ORDERS OF THE CATHOLIC CHURCH.

OBSERVATION SCHOOLS. — Schools connected with institutions for the training of teachers where the prospective teacher observes practical work of instruction in connection with his theoretical training. The term is used to distinguish such an affiliated school from those where the prospective teacher is allowed trial teaching usually termed a Practice School (*q.v.*) or a Training School. It is also distinguished from closely related schools which may be termed Experimental Schools (*q.v.*), which are used for educational experimentation under expert direction. The term Observation Schools, however, is used synonymously with the term Model School (*q.v.*).

OBSERVATIONAL GEOMETRY. — See GEOMETRY.

OBSERVATIONAL METHOD. — See OBJECTIVE METHOD.

OBSESSION — An impressive and persistent idea similar to a fixed idea, which holds the field of consciousness to the exclusion of normal ideas. The idea is of exaggerated importance and usually leads to certain abnormal actions. Although at times the ideas are understood by the individual to be abnormal, they cannot be restrained. Pathological action is not a necessary part of the obsession for many persistent ideas lead to no special action; any constant recurrence of one idea is properly called an obsession.

The commonest forms of obsession are fears relative to the performance of certain acts, or to the power or influence of certain conditions or things. The fear of walking under a ladder, of walking on the cracks of the sidewalk, of leaving a pin lying on the street, are examples of the commonest obsessions which, however, do not become pathological because of later education and of the demands of business or professional life. They may, however, lead to more marked abnormalities, such as the phobias (*q.v.*) The fear of open places (agoraphobia), the fear of closed places (claustrophobia), the fear of high places (acrophobia), the fear of fire (pyrophobia), are the most common of these.

Obsessions of doubt are also frequent. These are of having performed some action which should not have been performed, or not having done a thing or of having done it improperly, or of having given undue or improper credence to certain things, mainly religious. The so-called *delire de negation* may be considered an extreme example of this. The individual denies the existence of the world, the existence of his own body, and everything. This leads to delusions that he is unable to die and, if the emotional tone is depressed, he may believe that his sufferings are to continue throughout eternity. On account of the insistent idea the obsession eventually may

lead to the committing of crimes, to certain genital acts, to scruples, to disjointed thought, and to hypochondriacal ideas resulting at times in suicide. Here also belong the so-called simple monomanias (*q.v.*). The kleptomania has an insistent idea, he is obsessed, he must take the article which is close at hand; the dipsomaniac cannot withstand his insistent idea, he cannot let an opportunity to take alcohol go by, even though he must steal a drink; the pyromaniac must start a fire, the impulse cannot be controlled. There are also the doubters (*folie du doute*), who are forever considering the possibilities and proprieties and the values of certain actions. At times these are simple, the doubt referring to simple acts such as having closed the safe, or locked the door, or that the clothing has been improperly buttoned or fastened. These doubts lead to the repetition of the action. The man returns to his shop and examines the safe again, the man and woman feels of the buttons or hooks to see that they are properly fastened. When doubts are exaggerated, they may lead to the performance of the same act dozens of times. The questionings and objections and doubts sometimes, because they cannot be answered, result in an aboulia, in which condition the individual does nothing because he cannot decide whether a certain action will give a proper result.

These conditions are found in psychasthenia (*q.v.*), neurasthenia (*q.v.*), hysteria (*q.v.*), and in other functional neuroses and psychoneuroses. A special pedagogical interest lies in the facts that they usually begin in childhood on account of some mental accident, and that they develop as time passes. The treatment of these cases can be carried out only when the cause or causes are discovered, and with these as a basis a reconstruction and reeducation or perfection of habit in the individual is brought about. Both etiology and treatment indicate fully the importance to the teacher of a knowledge of the condition.

OCCIDENTAL COLLEGE, LOS ANGELES, CAL. — A college established in 1887 by men of Presbyterian faith for the purpose of providing opportunity for Christian education for the young people of Southern California. Three years later, having absorbed McPherron Academy, it was incorporated under the laws of the State of California as Occidental College of Los Angeles. During

the year 1911-1912 its enrollment numbered 300 and its teaching force twenty-two professors and instructors. The present campus, to which additional adjoining land has been added, contains twenty-five acres, and plant of three buildings, the old plant having been destroyed by fire in 1896. The college will move to a new site September, 1913. During the past five years the college has become non-denominational, and the academy has been discontinued. A. G. P.

OCCOM, SAMSON (1732-1792). — American Indian educator. He belonged to the tribe of the Mohicans and was educated at Moor's Charity School at Lebanon, Ct., conducted by Eleazar Wheelock (*q.v.*). He taught at New London, Ct., and for ten years he conducted an Indian School on Long Island. In 1766 he was sent to England by Dr. Wheelock to solicit the funds which secured the establishment of Dartmouth College (*q.v.*). He was a minister of the Presbyterian church, and devoted the remainder of his life to religious and educational work among the Indians. W. S. M.

OCKHAM (OCCAM), WILLIAM OF. — See SCHOLASTICISM; SCHOOLMEN.

O'CREAT. — N. O'Creatus, as he describes himself, was a pupil of Adelard of Bath (*q.v.*), and to this scholar he dedicates one of his books, a work on multiplication and division: "N. O'Creati liber de multiplicatione et divisione numerorum ad Adelardum Bathoniensem magistrum suum." The preface to this work begins as follows: "Prologus N. O'Creati in Heleceph ad Adelardum Betensen magistrum suum" The meaning of Heleceph (Helecp, Ars Helecp) is unknown, although there are several conjectures, as that it is from the Arabic *algeyfa*, a study. The life of O'Creat is as unknown as the curious word that he uses, for we know nothing of his birth or death or works. He lived in the twelfth century, and was probably a teacher of some distinction, acquainted with Arabic as well as with Latin. The name seems to show that he came from Ireland, and it is possible that he learned Arabic from Adelard, who was a master of this language. D. E. S.

ODO, ST. — See CLUNY.

ODOR. — Odors are the stimuli for the sense of smell. The general assumption is that odorous substances give off small particles which are borne in the air to the olfac-

tory membrane and there induce chemical changes in the nerve. What the chemical character is that serves to excite the nerve is not known, although there is some evidence that substances of similar chemical composition have similar odors. Practically all of the odorous substances belong in the fifth, sixth, and seventh groups in the periodic classification. Odors are all named from objects; there are no true names for odors.

OHIO NORTHERN UNIVERSITY, ADA, OHIO.—A coeducational institution established in 1871 as the Northwestern Ohio Normal School. In 1885 the name was changed to Ohio Normal University, and in 1898 this institution was sold to the Central Ohio Conference of the Methodist Episcopal Church, which obtained a new charter under the present title in 1904-1905. The following departments are maintained; commerce, engineering, law, liberal arts, music, pharmacy,

normal school, fine arts, and expression. Fifteen units of high school work are required for admission to the college of liberal arts. The usual college degrees are given. The enrollment of students in 1911-1912 was 1869. There is a faculty of thirty-eight members

OHIO, STATE OF.—Ceded by Virginia to the Federal Government in 1784, organized as a part of the Northwest Territory by the Ordinance of 1787, and admitted as the seventeenth state in 1802. It is located in the eastern part of the North Central Division, and has a land area of 40,740 square miles. In size, Ohio is about the same as Virginia, a little smaller than Pennsylvania, and about the size of England proper. For administrative purposes the state is divided into eighty-eight counties, and these in turn into townships, cities, incorporated towns, and special school districts. In 1910 Ohio had a total population of 4,767,121 and a density of population of 117 persons to the square mile.

Educational History.—The land ordinance of 1785, providing for the rectangular survey of lands in the Northwest Territory, in which "lot No. 16 in every township, for the maintenance of schools within the said township," was ordered to be reserved for sale, marks the beginning of educational legislation for Ohio. In the contract for the sales of tracts of land, made by the Continental Congress in 1787 with the Ohio Company, and in 1788 with John Symmes, lands for schools, religion, and a university were reserved and granted. (See NATIONAL GOVERNMENT AND EDUCATION) In 1799 the Northwest Territorial legislature enacted a law against trespass on school lands, imposing a fine of \$8 for any injury to certain specified trees, and \$3 for injury to any unspecified tree. This was the only territorial legislation in Ohio having any reference to education.

On the admission of Ohio in 1802, in return for a tax exemption for five years on all national lands sold, Congress gave the sixteenth section in each township to the inhabitants thereof, for the benefit of schools, and the new state put into its state constitution three clauses relating to education and learning. These declared that religion, morality, and learning should be forever encouraged, guaranteed equal benefits to the poor in the schools supported from the land funds, and permitted the incorporation of societies and institutions for the support of schools and the advancement of learning. In 1802 the legislature created the University at Athens, and in 1809 Miami University (*q.v.*) was founded. In 1803 the legislature incorporated the Trustees of the Erie Literary Society, in 1805 the Trustees of the Dayton Library, and in 1808 the legislature granted incorporation to Academies at Chillicothe and Dayton. For the next

nine years almost the only educational legislation was the chartering of such institutions, and in 1817 the necessity for these special acts was removed by the enactment of a general law for the incorporation of schools and library companies. The only other educational legislation up to 1821 was the enactment, in 1806 and 1810, of laws authorizing the organization of any school township having twenty voters, the election of three township trustees and a township treasurer to look after and care for the school sections, and further authorizing the trustees to divide the townships into such school districts as they might see fit, and to grant to any schools organized their share in the profits of the school land section. No other means of school support seems to have been provided before 1821.

The first public school law was enacted in 1821, but was so inadequate that the law of 1825 is usually regarded as the real beginning of the public school organization in Ohio. This ordered the trustees of the civil townships to organize school districts, retained most of the provisions of the Act of 1821 with reference to the duty of school officers, made the first provision for the certification of teachers, and levied a one half mill county school tax. The school revenues were still inadequate, and the rate bill was continued as before. The branches of study to be taught were reading, writing, and arithmetic. Three examiners of teachers were to be appointed by the county court of common pleas, who, in addition to examining teachers, were to visit and supervise the schools.

The year 1827 marks the establishment of the common school fund of the state. In 1824 Ohio petitioned Congress for permission to sell its school lands, which Congress granted in 1826. The law of 1827 authorized the sale, ordered the money to be placed in the State Treasury to the credit of the townships, and pledged the faith of the state to pay interest on the deposits at 6 per cent. In 1831 the salt lands, given to the state at the time of its admission to the Union, were also devoted to education. New general school laws were enacted in 1829, 1831, 1834, and 1836. Each was merely the combination of its predecessor with such minor amendments as had been enacted in the interval. In 1827 the minimum school tax on each householder was fixed at \$1, though this might be paid by two days' labor on the schoolhouse, a provision which continued until 1838. In 1827, also, all fines for immoral conduct in any school district were to be paid over to the district school funds. In 1829 the first special city school law (see CINCINNATI) was enacted, negroes were debarr'd from school privileges, the county school tax was increased to three fourths mill, and school district meetings were more fully provided for. The provisions for voting school district taxes, and the exemptions,

were somewhat minutely specified. A three months' school term and the first grading of teachers' certificates were also provided for. In 1831 the school district directors were constituted a body politic and corporate, a census of school children was provided for, the basis of apportionment was changed from householders to census children, and teachers' certificates were to be based on a knowledge of reading, writing, spelling, and arithmetic, with special certificates to women on reading, writing, and spelling only. In 1834 an assistant examiner of teachers for each township, to be appointed by the county board, was provided for. In 1833 and 1834 the fuel tax was provided for in the law, and school directors were authorized to furnish the quota of any one neglecting to do so, and to charge the same to the delinquent. In 1836 the county school tax was increased to one and one half mills, with permission either to county commissioners to levy two mills or to townships to levy an additional one and one half mills.

In 1829 there was organized at Cincinnati the Western Academic Institute and Board of Education, which in 1832 became the Western Literary Institute and College of Professional Teachers. For ten years this was almost the only strongly stimulating agency in education in the state. It sought to promote the diffusion of knowledge as to education, and to elevate the character and quality of the teachers of the state. Among its members were Albert Pickett, Lyman Beecher, Samuel Lewis, B. O. Peers, and Professor Calvin E. Stowe. Money was subscribed, an agent was sent to visit the schools of the state, and delegations appeared before the legislature in the interests of education. Under the influence of this society, Professor Calvin E. Stowe was commissioned by the legislature to visit Europe and to report on the systems of elementary instruction found there, and 10,000 copies of his report were ordered to be printed by the legislature in January, 1838. In 1836 a state convention for promoting education was held, and in 1837 the legislature was prevailed upon to make the beginnings of state school supervision, by the creation of the office of Superintendent of Common Schools. The Superintendent was elected by the legislature for a one-year term, and was to receive a salary of \$500. His duties were almost entirely statistical and clerical. Finally, in March, 1838, and largely as a culmination of these efforts, what has become known as the great school law of 1838 was enacted. This was based on the recommendations contained in the first report of the new Superintendent of Common Schools, and marked a great advance in school legislation for the state. It was based on the idea of strengthening the power of the state and of the townships at the expense of the districts. The office of State Superintendent of Common

Schools was continued, but changed to a three-year appointment, and the salary increased to \$1200. A state common school fund was created, as distinct from the common school fund or township fund, established in 1827. In this new fund were placed the salt lands, devoted to education in 1831; interest at 5 per cent on the Surplus Revenue, distributed in 1837 (see NATIONAL GOVERNMENT AND EDUCATION); the state's revenue from banks, insurance, and bridge companies, and some other minor sources of income. The income on all of these items amounted to about \$200,000 a year and this was to be distributed to the townships on the basis of the school census. A state school tax of one half mill was also voted a few days later, and the required county school tax was increased to two mills. For the townships, every township clerk was made *ex officio* township superintendent of schools with the usual supervisory duties. He was also to estimate the money needed to provide a six months' term of school, and to submit to the voters of the township the question of levying the tax. The township treasurer was also given the custody of all state, county, and township school funds, the district treasurers being left only the district taxes for building, fuel, and furniture. School directors, too, were given greater independence of action. They could now levy annually a tax of \$20. for incidental expenses without the sanction of the district meeting, and the old limitation of district taxation to resident property holders was withdrawn. All voters were now admitted to the district meetings. School directors were authorized to determine at what ages children could be admitted to school, and to permit instruction in a foreign language (German). Cities and towns were declared separate school districts, wherein the electors were to choose either three directors for the whole city or town, or one for each subdistrict (school). Directors in cities and towns were empowered to establish schools of different grades, and to make rules and regulations for their management.

The law of 1838 was the first comprehensive school law for the state, and was in the direction of a strong and efficient educational administration. It was, however, like much good early legislation, in advance of public sentiment, and the law was soon materially modified. In 1839 the county school tax was cut in half, the township taxes were reduced, and the township superintendents' supervisory powers were materially lessened. In 1840 the office of State Superintendent of Common Schools was abolished, and the duties of the office transferred to the Secretary of State. The clause in the law requiring reading, writing, and arithmetic to be taught in the English language was repealed, and German district schools were reorganized. The first attempt at a graded course of study was is-

sued this year. In 1842 the enumeration of children was taken from the township superintendent and restored to the district clerks, and the term of the district school director was lengthened from one to three years. In 1847 the county school tax was further reduced to two-thirds of a mill.

On the other hand, some constructive legislation for both city and district schools was enacted during this period. The city legislation began in 1829, when the first special city school law (Cincinnati) was enacted, and it was continued in 1839 by a special law for Zanesville, in 1845 for Columbus, in 1846 for Dayton, in 1847 for Akron, and in 1848 for Cleveland. Night schools were first authorized in 1839, but only for males. The Akron law, at first applying only to Dayton and Akron, was soon amended to apply to all cities and incorporated towns, two thirds of whose inhabitants petitioned the council for special city or town school organization. This law gave the Board of Education power to establish "a central grammar school where instruction should be given in the various branches and parts of study not provided for in the primary schools and yet requisite to a respectable English education." The Cincinnati central high school dates from 1847. In 1849 another similar law was enacted which gave the school corporations greater powers, and extended union school privileges to townships and school districts having 500 or more inhabitants. The Akron law and the law of 1849 mark the establishment of the graded and town school system in Ohio.

For the township and district schools, other minor legislation was enacted before 1853. In 1846 school districts were authorized to establish school libraries, and to expend therefor \$30 the first year and \$10 thereafter. In 1847 county teachers' institutes were authorized and funds for maintaining them provided. The Ohio State Teachers' Association held its first meeting this year. The same year county superintendents were authorized to be appointed in twenty-five specified counties, but this law was repealed in 1853. In 1848 the establishment of schools for negroes, debarred from educational privileges since 1829, was authorized, and the next year the establishment of separate schools for negroes was made optional. An effort to get better school returns was made by a law of 1848, requiring teachers to make an annual report to the township treasurer, but it was not until 1858 that complete returns from all of the counties were for the first time made. In 1849 the first advance beyond the 3 R's was made by a law adding English grammar and geography to the subjects for teachers' examinations, and to any school, on petition of three or more householders. In 1850 a law was passed creating a State Board of Public Instruction, state district supervision, state

uniformity in teachers' examination questions, and state life diplomas; but the legislature failed to appoint the five persons provided for, and the law never went into effect. A city superintendent of schools for Cincinnati was first authorized in 1850. In 1851 the law of 1838 was restored in most of its important particulars. The township clerk was restored to his full powers as township school superintendent, and given \$1 a day additional for time spent in school visitation. The annual district meeting remained strong, but district directors were now allowed to levy \$50 without a vote of the district, the county school tax was restored to 1 mill, and the income from the state common school fund was increased to \$300,000 a year.

In 1850 a new state constitution was prepared and adopted by the people. This contained but a brief article on education, merely guaranteeing the security of all educational and religious funds, directing the legislature to provide for free schools, and prohibiting sectarian aid from any school funds. Under this new constitution, the third important school law for Ohio (the Rice Act of 1853) was enacted, abolishing the rate bill and making other important changes and improvements. A State Commissioner of Common Schools, to be elected by the people for three-year terms, was created, and a state school tax of three mills, to provide free education for all, took the place of the \$300,000 lump sum previously distributed. A state tax of one tenth of a mill was also added for common school libraries. The county school tax disappeared, and township taxation for schools superseded district taxation. County superintendents were abolished, but county boards of examiners, to be appointed by the probate judge, were continued, and \$1.50 a day was now granted to them for their services. Orthography was added to the list of examination subjects for teachers. Evening schools were opened for the first time to both sexes; separate schools for colored pupils were permitted in districts having thirty or more colored pupils; and the minimum school term was increased from six to seven months. The beginnings of township control were made in the, at first nominal, subordination of the district system. The school districts were reduced to subdistricts and deprived of their corporate powers, though each retained three trustees. The school district meeting was also abolished, except for the annual election of one trustee. The subdistrict trustees still retained the power to elect teachers, inspect the schools, build and repair buildings, and purchase supplies. The clerk of each subdistrict board, together with the township clerk, now became a township school board, with the township treasurer, *ex officio*, as treasurer of the board. This township board was given oversight of all school property, estimated the township school tax,

made regulations relating to studies, textbooks, and discipline, and fixed the boundaries of the subdistricts. Township boards were authorized to appoint one of their own members as township school manager, though few such appointments were ever made. The control of any "central or high school" maintained by the township was vested in the township board. Any township might establish schools higher than the primary grade, if approved by the voters of the township. Cities and villages were given power to establish "central or high schools" without approval by the voters of the district. In 1854 it was stated that at "the commencement of 1847 there was not a single well-organized public high school in the state, now there are more than forty in which thorough academic education is given, besides nearly an equal number in which instruction is given in some of the higher branches." Following this important organizing law, there was no other important educational legislation for twenty years.

The new school code of 1873 was a codification rather than a new school law. All preceding legislation was repealed, inconsistencies were straightened out and conflicts of authority eliminated, and the whole was restated in new form. It made no new contributions to the development of the state's school system, nor did it add any important element to the administrative machinery. It is classed, nevertheless, with the laws of 1825, 1838, and 1853, as marking a fourth stage in the development of the state school system. Its chief additions were a classification of city and town school corporations; the separation of school government from municipal government; any school district (city, town, or township) was authorized to appoint a superintendent of schools; an examination in the theory and practice of teaching was added to the examination subjects for all teachers; teachers' institutes were required in all counties, and separate city institutes were authorized; an end was put to German schools by ordering all instruction to be in the English language; the state school tax was further reduced to one mill, while district taxation up to seven mills was permitted. The next new school code was not enacted until 1904, and in the interval a number of important school laws were added.

In 1875 the expenditure of school moneys for evening schools, for books, apparatus, etc., was authorized for any city, town, or special district. In 1881 all districts were permitted to spend school money for school library purposes, and in 1893 all districts were permitted to establish evening schools. In 1882 United States history, in 1888 elementary physiology, in 1896 civil government, in 1904 literature, and in 1911 agriculture were added to the list of teachers' examination subjects. In 1882 the State Teachers' Reading Circle

was organized and began its work. In 1887 an industrial department in Wilberforce University was established by the state. In 1888 the State Board of Examiners was increased to five, three grades of life certificates and four of county certificates were authorized, and boards of city school examiners were created. Still later, village boards of examiners were also created, so that little except the granting of rural certificates was left to the county boards of examination. In 1885 the union of township, village, and special districts to maintain a high school was permitted. In 1887 the laws requiring separate schools for colored pupils were repealed. In 1889 the first comprehensive school law was enacted, and this was amended and strengthened in 1890, 1893, 1898, and 1902. In 1891 an experience qualification was imposed for membership on county boards of examination. In 1885 the period for textbook adoptions, fixed at two years by the first legislation on the subject in 1871, was increased to five years, and boards of education were authorized to buy textbooks and supplies and to furnish them to pupils at cost. In 1890 a schoolbook board was created, to approve books and fix prices. In 1891 this board was authorized to contract with authors or compilers direct, and in 1894 all boards of education were permitted to supply free textbooks, and to levy an additional tax for the purpose.

In 1892 the process of subordinating the district system to township control, begun in 1853, reached its culmination in a law which abolished subdistrict trustees and created representative township boards to manage the schools of the townships. This constructive legislation was undone in 1898 by a law which restored the subdistrict director system, but two years later townships were permitted to abolish the subdistrict system by a vote of the people, and in 1904 the township was once more made the unit. In 1892 physical training in city schools was required, and in 1893 a schoolhouse sanitation law was enacted. In 1893 the kindergarten was included as a part of the public school system, and a local tax of one mill authorized therefor. In 1894 women were permitted to vote at school elections. In 1896 the United States flag was required on all schoolhouses. In 1898 the articulation of the county schools with the high schools was secured by a law providing for the examining and the awarding of diplomas to those completing the rural schools, and permitting any township board to pay the tuition of rural pupils at a high school. In 1898 two adjacent townships were permitted to unite to support a high school, and in 1900, and again in 1902, the payment of high school tuition was made mandatory. In 1894 the centralization of schools and the transportation of all pupils to a central school was begun in Kingsville Township, Ashtabula County;

in 1896 the same plan was permitted in three counties; in 1898 the plan was permitted to be put in operation anywhere in the state; and in 1900 a revised law gave the initiative to the township boards, or, if they failed to exercise it, to the people by initiative proceedings.

Although a number of recommendations had been made by the State School Commissioners looking to the establishment of a normal school for the state, Ohio took no action until recently. In 1886 the first appropriation was made, consisting of \$5000 a year, to Ohio University at Athens to establish a teachers' training course. This was done, but the appropriations grew steadily less, and in 1896 the course was dropped altogether. In 1900, after much agitation, and after receiving a petition containing over 20,000 signatures, the legislature finally made the first provision for normal schools in the history of the state. A state commission was appointed to locate one state normal school. In 1902 two state normal schools were created instead, by adding a normal school department to the two smaller state universities in the southern part of the state, — Miami University at Oxford and Ohio University at Athens. A State Normal School Commission was also created in 1902, to consider the location of additional normal schools. The Commission reported in 1903, recommending the creation of a State Board of Education of five, to have control of the schools, and to exercise a few other functions. No action was taken on this recommendation. In 1906 the legislature declared it as a state policy that the Ohio State University at Columbus might maintain a teachers' college, but should never maintain a normal department, and that the two state institutions in southern Ohio should not provide instruction extending beyond the A B and the A.M. degrees, thus clearly differentiating the work of the three state institutions. In 1910 two additional state normal schools were created, to be located in northern Ohio.

In 1902 the Brumbaugh law, classifying the school system of the state, and providing for three grades or classes of high schools, was enacted, and the child labor and compulsory education laws were re-written and harmonized. In 1902 a new municipal code was made necessary by a supreme court decision nullifying the Cleveland special legislation, and in 1904 a new and revised school code, the fifth for the state, was formulated and approved by the legislature. The school code of 1873 had been almost entirely changed by the amendments of thirty years. The new code not only gathered up and classified these changes, but itself made a number of additions of importance. The subdistrict system was finally eliminated, boards of education were given a four-year term, the school districts of the state were classified and their powers restated, school superintendents were given increased tenure and

powers, village boards of examination were abolished and the certification laws were revised, teachers were ordered to be paid for attending county institutes, uniform questions for all teachers' examinations in the state were made mandatory, and the approval of all local courses of study by the Commissioner was required. In 1906 a minimum salary law was passed, which required a salary of \$40 a month for an eight-month term. State aid for weak districts was provided to carry out the law. In 1909 two high school inspectors were authorized for the State Commissioner's office, and the State Inspector of Workshops and Factories was given power to inspect school buildings and to approve all schoolhouse plans. In 1910 the commission on the recodification of the laws made its report; the report was accepted by the legislature, and a new edition of the recodified laws was issued. In 1911 agriculture was added to the subjects to be taught in the public schools, and was made a required subject for teachers' certificates after August, 1912. The state was also to be divided into four agricultural districts, with a district supervisor of agricultural instruction to be appointed by the State School Commissioner for each. In 1912 a constitutional convention met to revise the constitution of the state.

Present School System.—At the head of the present school system of Ohio is a State Commissioner of Common Schools, elected biennially by the people. His duties are largely clerical and supervisory, with no important powers lodged in the state office. The duties of the State Commissioner include office work, visiting the judicial districts of the state each year, meeting school officials, delivering lectures, preparing blank forms and issuing the school laws, issuing an Arbor Day manual, preparing all questions for the examination of teachers and for eighth-grade examinations, and making an annual report to the Governor. He has supervision of the school funds and, on complaint, may appoint an examiner to examine into the funds of any district. All private and denominational schools make statistical reports to him each year. He has the appointment (1909) of two state high school inspectors, who visit the high and other schools of the state, assist at and inspect teachers' institutes, and virtually act as Deputy State Commissioners. He also has the appointment (1911) of four district supervisors of agriculture, who are also in effect state deputies, and are appointed for two-year periods at a salary of \$2000 a year. The State Commissioner also appoints each year one member of the State Board of Examiners. The State School Commissioner has few other functions. As in Massachusetts, what he can accomplish depends largely on the personality of the Commissioner himself. Excepting a State Board of Examiners, to grant life certificates, there are no state edu-

cational boards. The system is essentially decentralized.

With the exception of the years 1847 to 1853, Ohio has never had the office of county superintendent. A county board of examiners for teachers' certificates has existed since 1825, and still constitutes the only county educational authority. A county board of three is appointed by the probate judge, one each year for three-year terms. Two of the three have taught at least two years, and also within five years; all must be residents of the county; and each must not be connected with any private or parochial school, or with a book firm. This board holds monthly examinations for teachers' certificates, examinations for graduation from the common schools in April and May, and conducts a county grammar school commencement in August. The pay of the members is regulated by the number examined, and is small. The State Auditor apportions the school funds to the counties, and the county auditor makes the county apportionments, and receives and transmits all school reports.

The real authority and government of the schools of Ohio rests with the school districts, of which there are four kinds: (1) Each city is a city school district; (2) each village having a \$100,000 valuation, and others by majority vote, is a village school district; (3) each civil township, with any attached territory, and excluding separately organized villages or cities, is a township school district, and (4) any contiguous territory, outside of cities and towns, having \$100,000 valuation, may be organized as a special school district. Adjacent territory may be annexed to any school district, or transferred from one to another by mutual consent, or by petition and hearing before the probate judge. Except in cities, all school districts have boards of education of five members, elected at large, and for four-year terms, only part going out of office each biennium. Cities under 50,000 inhabitants have boards of education of from three to seven, elected similarly at large and for four-year terms while larger cities may vary from four to thirty-seven, part at large and part by subdistricts. (See CINCINNATI; CLEVELAND; COLUMBUS.) Women may vote at all school elections. Each board is a body politic and corporate, and may make rules and regulations for its own government, not inconsistent with law. The city, village, or township treasurer acts *ex officio* as treasurer for the district, but in special districts a district treasurer is appointed. In township districts, the township clerk acts *ex officio* as clerk of the district, but in other districts the board elects or designates the clerk. The clerk, or the clerk together with the superintendent, if there be one, makes an annual report to the county auditor. Township districts are subdivided into subdistricts, unless the same have

been abandoned and the township centralized. If the subdistricts still exist, which is the usual condition, a director is elected annually in each subdistrict to have charge of the school property, to provide fuel and repairs, and to act as a means of communication between the people of the subdistricts and the township board. The township board on its own initiative, and, on petition of one fourth of the electors, must submit the question of centralization to a vote. If carried, all subdistricts are abolished and the schools of the township are operated as a unit. Small schools may, however, be abandoned and the children transported.

Every board of education has charge of the school buildings in its district, may condemn land for school purposes, and may repair, rent, or build school buildings, within the limits of its funds. A graded course of study must be adopted and approved by the State School Commissioner. A sufficient number of schools must be maintained for not less than eight nor more than ten months, though boards in cities may provide vacation schools and playgrounds, in addition. Any school board may establish a public library, appoint a board of library trustees, and levy a tax up to one mill for its maintenance. If no public library is maintained, up to \$250 may be appropriated annually for school libraries. Boards may also found and maintain a museum in connection with the library. Cities may maintain special schools for tubercular children, and any school district may be authorized by the State School Commissioner to provide day schools for the oral instruction of the deaf. Cities may establish a city normal school, and may provide separate teachers' institutes. Any board of education may establish a high school, without a vote of the people, if the funds at hand will permit. High schools must be maintained at least seven months for third grade high schools, and at least eight months for all other classes. Any school district, on petition of twenty-five eligible pupils, must provide instruction in evening schools, to which adults may also be admitted. Districts may also provide instruction in manual training, domestic science, agriculture, or commercial work, or establish trade or vocational schools. Boards of education may appoint teachers, a superintendent, truant officers, medical inspectors, and a superintendent of buildings. In cities, the superintendent has the nomination of teachers, and city boards may appoint a school director, who acts as a business manager. Cities may employ a superintendent for any period up to five years, while in all other districts a superintendent may be employed from one to three years. Each board of education adopts its own textbooks for five-year periods, from lists furnished by the State School Commissioner, from publishers who will agree to provide books

at not over 75 per cent of the wholesale list price, and boards may either sell the books to the pupils at cost or provide free textbooks. All instruction must be in the English language, though instruction in German as a subject of study is permitted.

School Support.—The state now makes an annual appropriation from the treasury equal to \$2 for each child, six to twenty-one, in the state, not including married persons, as returned by the annual school census. This is approximately equal to the former one-mill state tax. The interest on the permanent school funds is also paid from the state treasury, and requires the equivalent of about one tenth of a mill. The interest on the sixteenth section funds is paid to the townships to which they belong; the state appropriations and interest on the state common school fund is made to the counties and school districts on school census; and the interest on the swamp land fund is apportioned to the counties on the basis of the number of males over twenty-one years in each. About 83 per cent of the school funds in Ohio come from local (district) taxation, the average levy in the townships (in 1910) being 7.71 mills, and 11.05 mills in the separate districts. No county school tax has been levied since 1853. Cities can not levy less than six mills, school boards in village and special districts may levy up to twelve mills, and in townships up to ten mills, while townships may levy five mills additional for high school purposes. Each district board estimates and levies the amount of money necessary for tuition, building, contingent, bond, and interest funds, and any district may levy five mills additional by vote of the people. Any city maintaining a municipal university may levy two mills additional for that purpose, and any township in which a state normal school is located may levy the same amount for it.

Teachers and Training.—The state employed 27,841 teachers in 1910, 3573 of whom were in high schools, and 8640 were men. For the training of future teachers the state now has four state normal schools (Athens, Bowling Green, Kent, and Oxford), and city training schools are maintained by five of the cities (Akron, Cleveland, Columbus, Dayton, and Toledo). Teachers' institutes are now maintained in each county annually, with about three fifths of the teachers in attendance. Schools may dismiss for institute for four days in cities and one week elsewhere, and teachers must be paid for such attendance. Teachers may be employed for from one to four-year periods in cities, and from one to three-year periods elsewhere. Any board of education may vote to establish a district pension fund, and after doing so must pay from 1 to 2 per cent of all income from taxation into this fund. All teachers accepting the provisions of the law also contribute \$2 a month to the fund.

After twenty years of service, half of it in the district, the Board may retire any teacher, and after thirty years of service, half of it in the district, a teacher may ask for retirement. The maximum pension is \$450. Teachers' certificates are granted for one, two, three, four, five, and eight-year periods, the one, two, and three-year certificates being classed as provisional certificates, and the five- and eight-year certificates being classed as professional certificates. The latter can be granted only after forty months of teaching experience, and are renewable. The four-year certificates are granted to graduates of professional courses in such normal schools and colleges, in Ohio or elsewhere, as have been approved by the State Commissioner of Common Schools. All certificates are also classified as (1) high school certificates, (2) elementary school certificates, and (3) special certificates. All examination questions are prepared by the State School Commissioner, and are uniform throughout the state. All high school teachers and superintendents of schools must hold a high school certificate. County boards of examination may recognize certificates from other counties, if they see fit. Life certificates are issued by the State Board of Examiners on the basis of experience and an examination in professional subjects. All teachers' certificates always date from September 1st, though twelve examinations are given each year. A state minimum salary law requires \$40 a month for at least eight months each year.

Educational Conditions.—While Ohio has a large city population and a number of rapidly growing cities, still 44.1 per cent of the total population live in the rural districts. The southern part of the state is more rural than the northern. About one eighth of the total population is foreign born, though the foreign born element lives largely in the cities. Ohio is a manufacturing as well as an agricultural state. The people of the state have always clung closely to local government, so that the school system is weak as regards central control. It is only recently that a very decentralized form of school administration has been in part superseded by township control. The county administration is as yet quite weak. The centralization of schools for a time made some notable progress in parts of Ohio, though the movement apparently has about come to a standstill. As late as 1910, only 178 of the 1319 townships in forty-six of the eighty-eight counties reported any degree of centralization. One fourth of these townships were in four counties, and centralization had been completed in only fifty-five townships. Forty townships have also employed township superintendents. An eight months' school term is required by law, and state aid has been granted to weak districts to enable them to pay the minimum salary and still provide an

eight-months' term. The school library system has been well developed, as have also the traveling libraries sent out by the Ohio State Library.

Secondary Education.—The high school has had a marked development in Ohio, there being about 850 high schools in the state. Nearly one fourth of these are township or township-union high schools. No special state aid is granted for secondary education, the high school being a tax on the district maintaining it. The high schools of the state are divided into three classes, four-year, three-year, and two-year. The two-year schools alone are allowed to drop to terms of seven months. There are two state high school inspectors, and the state university examiner also visits the high schools, but there is no state course of study for them.

Higher and Special Education.—The Ohio State University (*q.v.*) at Columbus, founded in 1870 as an agricultural and mechanical college and later developed into a large and important institution, stands as the culmination of the public school system of the state. The Ohio University (*q.v.*) at Athens and Miami University (*q.v.*) at Oxford are state institutions of collegiate rank and state normal schools combined. The state also grants aid for an industrial department for the colored race in Wilberforce University (*q.v.*). Toledo University and the University of Cincinnati (*q.v.*) are municipal institutions. Ohio is distinctively the state of small church colleges, there being twenty-six, with six others now classed as nonsectarian, although most of these were once denominational. Seven of these colleges date from before 1840, and almost all from before 1885. Sixteen of these have less than \$150,000 of endowment funds to-day, and most of them are small and struggling institutions.

Of special institutions, the state maintains the State Institution for the Feeble-minded; the State School for the Blind; and the State School for the Deaf, all at Columbus; and the Ohio State Reformatory, at Mansfield. Two cities report day schools for the deaf

OHIO STATE UNIVERSITY

OHIO STATE UNIVERSITY, COLUMBUS, OHIO.—An institution which grew out of the Morrill Act of 1862, commonly known as the Land Grant Act. In 1864 the legislature passed an act accepting the grant, but not until 1870 was the law enacted providing for the organization of the Ohio Agricultural and Mechanical College. In consideration of the location of the College, Franklin County provided a fund of \$300,000 by a bond issue. This was subsequently increased by \$25,000. Three hundred and thirty acres of land lying within the city limits west of High Street and three miles north of Capitol Square were purchased as a site. Additional purchases of adjacent land make an estate of 453 acres.

The College was opened for students on September 17, 1873. In 1878 the legislature reorganized the institution, changed the name to the Ohio State University, and made the first appropriation in the history of the state for higher education. The proceeds of the sale of the public lands were by law made a part of the irreducible debt of the State upon which the State pays 6 per cent interest. The statutes provide that all money given to the university, unless otherwise directed by the donor, shall become a part of this irreducible debt which is but another name for an endowment fund. That fund for general purposes now amounts to \$167,687.62. The fund for designated purposes amounts to \$65,631.31, making a total of \$233,318.93.

The institution is governed by a board of seven trustees, appointed by the Governor and confirmed by the Senate, for terms of seven years. The organization provides for seven colleges as follows: Agriculture; Arts, Philosophy and Science; Education; Engineering; Law; Pharmacy, and Veterinary Medicine. There are at present (1912) twenty-six buildings used for instruction, three residences, Oxley Hall for young women, and the Ohio Union Building for general social and clubhouse purposes. The value of the plant, including the endowment mentioned above, as shown by the inventory is \$5,624,933.70. The total income for the year ending June 30, 1911 was \$924,611.11. The enrollment for the year ending June, 1911 was 3439. For the same year 422 degrees were granted. The graduate school was organized in September, 1912. The University faculty is composed of all persons having the rank of professor and now numbers eighty-three. The College faculties consist of all persons having the rank of assistant professor, associate professor, and professor, and now numbers 153. The instructional force includes about seventy additional members. The following have served as president: Edward Orton, 1873-1881; Walter Quincy Scott, 1881-1883; William Henry Scott, 1883-1895; James Hulme Canfield, 1895-1899; William Oxley Thompson, 1899-. W. O. T.

OHIO WESLEYAN UNIVERSITY

OHIO UNIVERSITY, ATHENS, OHIO.—The oldest higher institution of learning in the "Old Northwest." Before Ohio was admitted to statehood the Territorial Legislature, in session at Chillicothe on Jan. 9, 1802, made provision "that there shall be an University instituted and established in the town of Athens." The institution was to be named the American Western University. The Ohio State Legislature reenacted the provisions of the Territorial Act, with but few changes, by another act dated Feb. 18, 1804, which gave the name Ohio University to the institution to be established and has ever been regarded as the charter of Ohio University. Students were admitted in the spring of 1808, when Rev. Jacob Lindley, a Princeton graduate, was put in charge of its educational work. The whole number of degree graduates, of baccalaureate rank, in the history of the university, is: men, 669; women, 159; total, 828. The total number of different students enrolled increased from 405 in 1901 to 1832 in 1912. There is a faculty of seventy-five members.

The university buildings are twelve in number, not including five buildings occupied as residences. Conservative valuation of the property of the University is \$1,500,000. The financial support of the university is derived from three sources, namely, the mill-tax, special appropriations, and local receipts from incidental fees, rents, and interest on permanent funds forming a part of the irreducible debt of the state of Ohio. Receipts from all these sources, in 1911, amounted to \$253,366.05. Salary payments for the fiscal year ended Nov. 15, 1911, amounted to \$100,310.08, of which amount the sum of \$81,095.52 was for teaching service exclusively.

Two degrees are given in the College of Liberal Arts, — A.B. and B.S. The degree of B.S. in Education is given those who complete the four-year courses in the State Normal College. To receive either of these degrees the student must have a credit of not less than 120 semester hours based upon at least fifteen units of secondary work. The field of instruction covered is shown by the following classification of colleges and departments: college of liberal arts; the state normal college; the college of music; the college of oratory; the school of commerce; the department of physics and electrical engineering, and the department of mathematics and civil engineering. A. E.

OHIO WESLEYAN UNIVERSITY, DELAWARE, OHIO.—Was founded under the patronage of the Methodist Episcopal Church in 1841, when an academy was opened. The charter was granted in 1842, and in 1844 the College of Liberal Arts began its work. In 1877 the Ohio Wesleyan Female College, established in Delaware in 1853, was incorporated in the university. Since this time the

OKLAHOMA COLLEGE

university has been coeducational in all departments. In addition to the college, the university now maintains an academy, and a Conservatory, including a School of Music and a School of Fine Arts, both established in 1877. The policy of the institution in recent years has been to enlarge the work and increase the efficiency of the college. Accordingly, the Cleveland College of Physicians and Surgeons, established in 1863 and made a part of the university in 1896, was in June, 1910, given over to the Medical Department of Western Reserve University. A School of Oratory, established in 1894, is now organized in connection with the college. A School of Business, established in 1895 and since 1908 organized as a part of the academy, was discontinued in June, 1912. The government of the institution is in the hands of a Board of Trustees elected by the Ohio, the North Ohio, the Cincinnati, and the Central Ohio Conferences of the Methodist Episcopal Church, the Association of Alumni, and five trustees-at-large elected by the Board. Students are admitted to the College by certificate from representative high schools or by examination. The entrance requirements are fifteen units. Undue specialization in elective work is guarded against by the distribution of subjects in groups, and the careful limitation of the student's courses in each. To differentiate the B.A. degree, a minimum of one year's work in college Latin or Greek is made a part of the language requirement; and for the B.S. a larger requirement in mathematics and science is provided than for the B.A. The total enrollment of students in 1912 was 1249. Of these 912 were in the college, 113 in the academy (including the School of Business), and 224 in the Conservatory. The faculty includes twenty-six persons of professorial grade, and forty instructors and assistants. The Rev. Herbert Welch, D.D., LL.D., is President.

H. W.

OKLAHOMA AGRICULTURAL AND MECHANICAL COLLEGE, STILLWATER, OKLA.

— A state institution organized in 1891 as a land grant college. The college is at the head of a system of state agricultural schools. It provides courses of instruction in agriculture, mechanical arts, engineering, military science, domestic science, training of teachers, and the related branches required by law. The college plant embraces eleven buildings and 1000 acres of land. Two years of high school work are required for entrance to the freshman class. The degree of B.S. is conferred in the different divisions of the college. The enrollment of students in 1911-1912, including all attending special and short courses, etc., 2100. The faculty includes seventy-one members.

OKLAHOMA STATE BAPTIST COLLEGE, BLACKWELL, OKLA.

— A coeduca-

OKLAHOMA, STATE OF

tional institution opened by the Oklahoma Baptist Convention in 1901. There are maintained an academy, college of liberal arts, college of fine arts, and business college. The entrance requirements to the college of liberal arts are fifteen units of high school work. The degree of B.A. is conferred. The enrollment in 1911-1912 was 208, and the faculty consisted of seventeen members.

OKLAHOMA CHRISTIAN UNIVERSITY, ENID, OKLA.

— A coeducational institution opened in 1908. A preparatory school, colleges of liberal arts, bible, music, and business, schools of oratory and fine arts, a teachers' college, and hospital training school for nurses are maintained. The entrance requirements to the college of liberal arts are fifteen units of high school work. The following degrees are conferred: A.B., B.D., and A.M. The enrollment in 1911-1912 was 350 in all departments. The faculty consists of twenty-two members.

OKLAHOMA, STATE OF. — Originally a part of the Louisiana Purchase, and set aside for Indians in 1834. In 1848 the slender western extension was obtained from Mexico, and for a long time was known as the Public Land Strip. This strip and the western half of the present state were opened to settlement, April 22, 1889, and were organized as Oklahoma Territory in 1890, while the eastern half continued as an Indian reservation up to 1898, when a territorial form of government was provided for it also. In 1906 Congress authorized the two territories to unite and to apply for admission as one state, and in 1907 the two were admitted together as the forty-sixth state. Oklahoma is located in the western part of the South Central division. It has a land area of 69,414 square miles, which is about the same size as the six New England states and New Jersey combined. For administrative purposes the state is at present divided into seventy-six counties, and these in turn are divided into cities, towns, and school districts. In 1910 Oklahoma had a total population of 1,657,155, and a density of population of 23.9 persons per square mile.

Educational History. — On the opening of Oklahoma Territory to settlement the inrush of settlers was very rapid. On the first day, 20,000 people crossed the border, and the first night Guthrie, which in the morning had been a vacant plain, had a population of 10,000 people. Before the end of the year, 60,000 people were in the territory, and in the next ten years the population increased over 400 per cent. Government Indian schools had existed in parts of the territory for some time. The first white schools were opened in Guthrie, El Reno, Kingfisher, and some other towns in 1889. The first high school was opened in Kingfisher in the same year. In the organic

act of 1890 Congress gave the new territory \$50,000 to be used in organizing the first schools. The first territorial legislature in 1891 enacted a detailed school law, which provided for the township form of organization; for township boards, with important educational functions resting with the secretary; for county superintendents, a Territorial Superintendent and Auditor combined, and a Territorial Board of Education; for territorial diplomas, and for three grades of county certificates, with uniform examination questions prepared by the Territorial Board of Education; normal teachers' institutes; and for a free textbook system, but with no appropriation to carry it into effect. This law laid down the main outlines of the present school system. A State University, an Agricultural and Mechanical College, and the State Normal School, at Edmond, were also created in 1891. In this year Congress authorized the Governor of the Territory to lease the school lands by public bids, for periods not exceeding three years; so these lands have brought in some income for the schools from the first. The township system was soon found to be unsuited to the needs of the new state, and was abandoned in 1893 for the district system, with district meetings and district boards, and this form of organization has since been retained. A new school law was enacted at this time, based, in large part, on the law of 1891, and thus 1893 code still remains as the substantial basis of the present school laws. The school legislation since 1893 has been more in the nature of additions than fundamental changes in the system then laid down.

In 1907 statehood for the two territories combined was attained and the new state began the task of organizing schools in the old Indian Territory, which had previously been practically without public schools. A few tribal common schools, manual labor institutions, and seminaries existed for the Indian population, and in some of the towns common schools for the whites had been formed, though none of the latter had existed over nine years, and most of them had been formed within the two to five years preceding statehood. There were no rural schools, and more than 150,000 children of school age had no opportunities for schooling. By the end of the first year, 2200 districts had been organized and schools established, and the beginning of the school year 1908-1909 saw 3441 rural schools in the old Oklahoma and 2200 in the Indian Territory, and about 3000 teachers in addition in city and town school systems in Oklahoma proper, or a total of 5641 school districts and about 9900 teachers employed in the new state nineteen years after settlement.

The state constitution of 1907 guaranteed the perpetuity as trusts of all lands and funds given for education; directed the legislature

to establish and maintain a system of free schools, in which all the children of the state should be educated; provided for compulsory education during the period from eight to sixteen, directed that separate schools for the negro race be established and maintained with equal accommodations; provided for a uniform series of textbooks for the schools; directed the legislature to provide for instruction in the elements of agriculture, horticulture, stock feeding, and domestic science; vested the supervision of the schools in an *ex officio* State Board of Education; gave to the State Board of Agriculture the supervision of the state agricultural and mechanical colleges; provided for a Board of Commissioners to manage the school lands and funds; and provided for the election of a State Superintendent of Public Instruction, and for a county superintendent of public instruction for each county. The legislature of 1907-1908 made but few changes in the school law, the law of 1893 still being in use in large part. In addition to a few minor changes in the law this first legislature revised the textbook law, the normal institute law, and the separate school law. It also established the Oklahoma School for the Deaf at Sulphur; the Oklahoma School for the Blind at Fort Gibson; a home for destitute children at Pryor Creek; and a State School of Mines at Wilburton. A State Commission on Agricultural and Industrial Education, to establish a district secondary school of agriculture in each supreme court district in the state, at the rate of two a year; and an addition to the certification law to provide that all teachers, after 1909, must hold certificates covering agriculture and allied branches, were added in 1908. In 1909 a new salary schedule for county superintendents was adopted. In 1910 cities organized under charters were given liberty to determine the number and method of election of boards of education.

The legislation of 1911 was of fundamental importance. The most important measure was the reorganization of the State Board of Education. The constitution of 1907 had provided that, until otherwise ordered by the legislature, the State Board of Education should consist of the Governor, Superintendent of Public Instruction, Secretary of State, and the Attorney-General. In 1911 a new State Board of seven members, with greatly enlarged powers, succeeded to the powers formerly exercised by the old State Board of Education, the State Textbook Commission, and the boards of regents of the several state institutions. A constitutional amendment was also proposed to the people giving to the legislature power to levy taxes for schools, to provide a method for the distribution of the proceeds (the constitution of 1907 required a census basis of distribution), and to provide for state aid to secure a five months' school throughout

the state. The State Superintendent was empowered to appoint a State Inspector of Schools, at \$1800 and expenses, and county superintendents were given a clerk and enlarged allowances for visitation. A "union-graded or consolidated school district fund" was created, to be derived from the sale of Section 33 lands in Green County, the proceeds of which are to be distributed to the different counties approximately in proportion to the school census, and to aid in the construction of buildings for union and consolidated school districts. County superintendents had added to their powers that of employing teachers for all minority race (usually colored) school districts.

Present School System.—At the head of the present state school system of Oklahoma is a State Superintendent of Public Instruction and a State Board of Education. The State Superintendent is elected by the people for four-year terms, while the State Board consists of the State Superintendent as president, *ex officio*, and six persons, two of whom must be practical schoolmen, appointed by the Governor for six-year terms. Two of the appointed members go out of office each biennium, thus giving a continuing body. Once appointed, the members can be removed only for cause. The appointed members receive \$6 a day and expenses for serving. The president may appoint a secretary at \$2000 and a stenographer at \$1200. This board has general supervision of the public schools and the state institutions of the state. It formulates courses of study for the common and high schools, the teachers' and pupils' reading circles, the county normal teachers' institutes, and the higher educational institutions of the state; it formulates rules and regulations concerning teachers' certificates; prepares all questions used at the examinations, and examines applicants for certificates; it prepares questions for the examination of graduates from the eighth grade of the common schools; it classifies the public schools of the state, and accredits schools; and it makes reports to the Governor and legislature, and prepares estimates for the educational appropriations. The board also succeeds to the powers of the former board of textbook commissioners, and selects and adopts a uniform series of textbooks, supplemental books, registers, reports, maps, charts, globes, and apparatus for the schools of the state, fixes their sale price, and makes contracts with publishers and manufacturers to furnish the same. Succeeding the boards of regents for the different state institutions, it controls the educational policy of the higher and special institutions of the state. A State Board of Land Commissioners, consisting of the Governor, Secretary of State, Auditor, State Superintendent, and president of the State Board of Agriculture, looks after the school lands and funds of the state. A State

Commission on Agriculture and Industrial Education, consisting of the State Superintendent, the president of the State Board of Agriculture, and the president of the Agricultural and Mechanical College, and working under the direction of the State Board of Education and in harmony with the Agricultural and Mechanical College, the normal schools, and the State Board of Agriculture, has charge of the establishment of the secondary schools of agriculture in each judicial district. The State Superintendent of Public Instruction acts as the executive officer of the State Board of Education, and, as such, has general supervision of the instruction in the public schools of the state. He gives opinions to city and county superintendents on disputed educational matters, publishes the school laws, visits each county each year, approves of the arrangements made by county superintendents for county normal teachers' institutes, receives reports from school officers, and makes a biennial report to the State Board of Education and to the Governor. He is *ex officio* a member of the State Board of Education, the State Board of Land Commissioners, and the State Commission on Agricultural and Industrial Education. He has the appointment of a State Inspector of Schools, at \$1800 and expenses, who acts for and with him in visiting schools.

For each county there is a county superintendent of public instruction, elected by the people for two-year terms. He receives a salary of from \$1200 to \$1800, according to the size of the county; receives his actual expenses for one visit to each school each year; and is also allowed to appoint a clerk at \$600 a year. He has the general supervision of the schools of his county. He visits the schools and examines the instruction and the material conditions; confers with the district school officers, encourages teachers' associations, and holds a public meeting in each school district once each year for the consideration of educational questions; organizes a county teachers' normal institute each summer for the academic and professional instruction of his teachers; receives reports from the district clerks, appoints to fill vacancies on the district school boards, and provides each district with the necessary books, blanks, and registers; divides the county into school districts, black and white, and rearranges the same; appoints the teachers for the minority race (usually colored) schools in school districts; keeps a record of all teachers employed, of the semiannual apportionment of school funds, and of all his official acts; and makes a quarterly and an annual report to the State Superintendent.

All cities of the first class constitute separate school districts and may provide for the number, manner of election, and terms of their boards of education. In other cities,

two are elected from each ward, for two-year terms, one half going out of office each year. All voting for boards of education must be on separate ballots. City boards are bodies corporate, and, excepting the treasurer, elect their own officers; have control of the city school property; may establish kindergartens and high schools as desired; may elect a city superintendent, who holds office at the pleasure of the board; may examine their own teachers, through an examining committee, consisting of the city superintendent and two persons appointed by the board; and may levy their own taxes, up to the limit allowed by law (seven mills for all city purposes, schools included).

Each county is divided into a number of school districts, for each of which the people, in annual district meeting in June, elect a district board of three, consisting of a director, clerk, and treasurer. One is elected by the annual meeting each year, and the county superintendent fills any vacancies on the board. The district meeting also has power to vote taxes, locate or change the location of schools, authorize the sale of school property, advise the district board as to litigation, and may determine the length of school term, above three months and less than nine. The clerk of the board attends to all reports and clerical matters, while the treasurer receives and pays out all moneys belonging to the district. The Board employs all teachers, manages the schools according to the law, and cares for the school property. If there are colored pupils in the district, they are transferred to some adjacent district, if less than ten in number, and separate schools must be maintained for them if more than ten. Separate school boards are also provided for in the latter case. The same holds true for a small number of white pupils in a colored district. In all minority race districts the teacher is appointed by the county superintendent, and the expense of maintenance is paid from a county tax, levied for the purpose. County commissioners may also provide a schoolhouse, at county expense, for the minority race, when the district is unable to do so. Equal equipment and instruction is to be furnished the two races.

Educational Conditions. — The white population is increasing so rapidly that the proportion of Indians and negroes, though numerically increasing in themselves, is rapidly decreasing. In twenty years, from 1890 to 1910, the white population increased eight and one third times, the colored population seven and two thirds times, and the Indian population increased but one fourth. The total population in 1910 was 87.2 per cent white, 8.3 per cent negro, and 4.5 per cent Indian. The eastern part of the state (the old Indian Territory) contains about two thirds of the negroes and about five sixths

of the Indians. The white population is over 96 per cent native born. About 80 per cent of the population live in the rural districts, though the cities are increasing in population faster than the rural districts. The western part of the state has but a small percentage of illiteracy, and that in the eastern part, chiefly Indian and negro, is decreasing rapidly. The state is essentially an agricultural state with great future agricultural and mineral possibilities. In time it will be one of the richest of our states, and the large endowments for education and the intelligent character of the white population insure the development of a very important state school system.

The rural schools are graded, the standards for certification are up to the average, and a good graded course of study is in use. Union-graded schools and the consolidation of districts and the transportation of pupils are permitted. Though a young state, Oklahoma has already made greater progress in the consolidation of small schools than have many of the older states. Eighty-six consolidated districts were reported as formed by 1911, and the new "union-graded or consolidated school-district fund" will do much to help the consolidation movement. Agricultural instruction has recently been made a very important part of the instruction, the law of 1908 requiring that "the elements of agriculture, horticulture, animal husbandry, stock feeding, forestry, building roads, domestic science, and elementary economics" shall be a part of the instruction for all public schools. Since 1909, teachers have been required to show some knowledge of agriculture for certification. All rural school sites must not be smaller than one acre. All schools must be taught in the English language. The state has, for its needs, a relatively good compulsory education law. All children, eight to sixteen years of age, not disabled or incapacitated, must attend school from three to six months each year, as determined by the school board and the people of each district. All indigent pupils are furnished the necessary books to enable them to attend, and the children of a widowed mother, who is dependent on their labor for support, are, upon investigation, given scholarships, under which the county pays the mother the requisite maintenance. Any school board may appoint truant officers to enforce the law. A small school library fund is set aside in each district for the purchase of books. Women may vote at all school elections and on the same terms as men.

School Support. — Oklahoma was treated most generously by Congress on its admission to the Union. Sections 16 and 36 in Oklahoma proper, previously reserved, were given to the state for its permanent common school fund, and \$5,000,000 in gold was given to the state in addition in lieu of

the similar grants in the Indian Territory. The school section grants totaled 1,413,083 acres, and the minimum sale price was fixed at their appraised value. The lands have been valued at an average of \$20 an acre and recent sales have markedly exceeded this sum. It is probable that a permanent school fund of from \$40,000,000 to \$50,000,000 will in time be built up from these land grants. The 5 per cent fund (see NATIONAL GOVERNMENT AND EDUCATION) was also granted for the permanent school fund. In addition to these grants for common schools, Section 13 in each township (706,540 acres) was also granted to the state, to be used, one third for the State University and the University Preparatory School, one third for the normal schools of the state, and one third for the agricultural and mechanical colleges for the two races. Section 33 was granted to the state for charitable and penal institutions and for public buildings, and part of this grant will also go for educational purposes (schoolhouses). In addition to these grants, and in lieu of the swamp land and internal improvement act grants (see NATIONAL GOVERNMENT AND EDUCATION) Congress made the state the following specific grants:—

For the State University	250,000 acres
For the University Preparatory School	150,000 acres
For the Agricultural College (white)	250,000 acres
For the Agricultural College (colored)	100,000 acres
For the State Normal Schools	300,000 acres
Total specific grants	1,050,000 acres

These grants should produce even more than the section grants for common schools, as the state was able to locate these grants on any unoccupied government land, instead of taking fixed sections of land.

The interest on the state school fund and the income from the lease of school section lands is apportioned semiannually to the counties and districts on the basis of the number of children in each, six to twenty-one years of age. This is worth about \$1 80 per pupil per year at present. A constitutional amendment, to be voted on in 1912, proposes the authorization of a state tax and state aid to maintain a five months' school and gives the legislature power to change the basis of apportionment. In each county, all fines, penalties, forfeitures, proceeds of estrays, and marriage licenses are added to the county school fund, and county commissioners may also levy in addition a county school tax, but the total for all county taxes for current expenses, including schools, must not exceed six mills. This, together with the state funds received is apportioned to the districts on the school census basis. Counties supporting a county high school may also raise one mill additional for county high school purposes. Each school district may, in addition, vote an annual district tax, up to five mills, for all

school purposes, and distribute this tax for different school purposes as it sees fit.

Teachers and Training.—The state employed 10,020 teachers in 1910 for the 5820 school districts in the state. Only about 8 per cent of these were teachers in the colored schools. County teachers' certificates are of three grades and are issued on examination for one, two, and three years, respectively. A temporary certificate is also issued and is much used. In each county a summer normal teachers' institute of from two to six weeks is held, and teachers attending this may have their certificates renewed. These summer normal institutes follow a course of academic and professional work outlined by the State Board of Education, and all institute conductors and instructors must be certificated by them. Four examinations for certificates are held each year. First-grade certificates are valid in any county in the state; second-grade certificates only in counties adjacent to the one in which they were issued; and third-grade certificates only in the county of issue. State certificates and diplomas are also issued by the State Board of Education. For the training of new teachers the state maintains six state normal schools, as follows. —

The Northeastern State Normal School, at Tahlequah.
 The Southeastern State Normal School, at Durant.
 The East Central State Normal School, at Durant.
 The Central State Normal School, at Edmond.
 The Northwestern State Normal School, at Alva.
 The Southwestern State Normal School, at Weatherford.

Secondary Education.—Any district, town, or city may establish a high school, as may any county. Consolidated schools or union school districts may also establish a high school as a part of the regular instruction. Only a few county high schools have so far been established, but most of the cities and towns have provided them. A number of the centralized schools have a good high school as a part of the instruction provided, and the number of such schools may be expected to increase rapidly under the new (1911) state building aid provided. In 1911, 435 school districts reported classes above the eighth grade, and fifty-one accredited high schools also were reported. The University Preparatory School, at Tonkawa, is a large state secondary school for whites, offering the classics, science, modern languages, business courses, and instruction in art, domestic science, manual training, music, and military tactics. A second school of this type was established in 1911 at Claremore. In 1908 the first two of the state agricultural high schools for whites were established at Warner and Tishomingo; in 1910 four more were established at Broken Arrow, Helena, Lawton, and Goodwell. These schools are to be agricultural and industrial schools of secondary grade, and must provide instruction leading to the agricultural and mechanical colleges and to

the state normal schools. The State Agricultural College is to be the technical head of this agricultural system of education, and is to issue a course in agriculture and related subjects for the elementary and secondary schools of the state. Each state agricultural high school must have at least eighty acres of land, and must conduct an experimental farm and offer short courses for farmers each winter. Twenty thousand dollars was appropriated by the state for a building for each school.

Higher and Special Education. — The State University at Norman, the State Agricultural and Mechanical College at Stillwater, the State Industrial Institute and College for Girls at Chichasha, and the Colored Agricultural and Normal University at Langston stand as the culmination of the educational system of the state. The State School of Mines at Wilburton is also a part of the state's higher educational system. The denominational college has found but little demand for its services so far in the state, and only four are reported. All of these are institutions of very limited endowment. The Oklahoma Industrial Institution for the Colored Deaf, Blind, and Orphans at Taft; the Oklahoma School for the Blind at Fort Gibson; the State School for the Deaf at Sulphur; the State Orphans' Home and School for Destitute Children at Pryor Creek; the State School for the Feeble-Minded at Enid; and the State Training (Reformatory) School at Paul's Valley, are the special institutions supported by the state. OKLAHOMA, STATE UNIVERSITY OF, NORMAN, OKLA. — A coeducational institution established at Norman by act of the territorial legislature in 1892. The following schools and colleges are maintained. college of arts and sciences (1893); school of pharmacy (1893, 1908); school of medicine (1910); school of fine arts (1903); school of applied science and school of mines (1904); summer school (1908); college of engineering (1909); school of law (1909); school of teaching (1909). The entrance requirements are the completion of four years of high school work. The usual degrees are conferred on graduates and undergraduates on the completion of the appropriate requirements. The university is supported from the general revenue of the state and from income derived from lands granted by Congress. The enrollment in all departments in 1911-1912 was 793. The faculty consists of ninety-seven members.

OLD AGE. — See SENESCENCE.

OLDENBURG, GRAND DUCHY OF, EDUCATION IN. — See GERMAN EMPIRE, EDUCATION IN.

OLFACTORY SENSATIONS. — The sense organ of smell is the olfactory membrane in the upper part of the nasal cavity, where the endings of the olfactory nerves come to the surface. The organ is stimulated by chemical responses induced by the particles of the odorous substance borne in the air. It is not known how many simple smell qualities there may be. That there are specific qualities with distinct structures is probable from the fact that when the nose has been fatigued for one odor, certain odors will not be noticed, while others will give sensations of normal intensity. Disease may also render one insensitive to several odors, while still normally sensitive to others. These experiments and observations have not been carried far enough to give a complete classification of smells.

OLIVER, HENRY KEMBLE (1800-1885). — Leader in the movement for child labor legislation, was graduated from Dartmouth College in 1818. He was principal of high schools at Salem, Mass., 1819 to 1830, and of a private secondary school from 1830 to 1844. He was Adjutant-general of Massachusetts for four years. In 1848 he engaged in the textile industry at Lawrence, and during the next eighteen years he added to his business duties enormous public labors. He was member of the school committee of Lawrence, mayor of the city, and member of the state legislature. He gave up business in 1866 to accept a post as agent of the Massachusetts State Board of Education. He made extended studies of the conditions of factory children and was one of the earliest advocates of child labor laws. In 1869 he was made chief of the Massachusetts Bureau of Labor Statistics. Under the administrations of Horace Mann and George S. Boutwell (*qq v.*), Mr. Oliver rendered important service as an institute lecturer in Massachusetts. His publications include numerous papers on education and a series of schoolbooks on music. W. S. M.

OLIVET COLLEGE, OLIVET, MICH. — A coeducational institution founded in 1844 by Mr. J. J. Shipherd eleven years after he

founded Oberlin. From the first it has been undenominational. The Congregationalists partially adopted the college, and it is now known as the Congregational College of Michigan, although without any organic relation to the denomination. Olivet has been vitally connected with the educational interests of Michigan. Its professors have served for many years in the office of the State Superintendent of Public Instruction and on the State Board of Education, and through their public lectures and published bulletins have had marked effect on the educational development of the state. The present value of the grounds, the fourteen buildings, equipment, and endowment amounts to about \$600,000. The library, museum of natural history, and equipment for teaching sciences are exceptionally good. The usual undergraduate departments, including music, are maintained. The entrance requirements for all students who intend to proceed to the degree (B.A.) are fifteen units of high school work. The enrollment in 1910-1911 was 238 students. The faculty consists of twenty-four members.

E. G. L.

OLMSTED, DENISON (1791-1859).—College professor and author of science textbooks; was graduated from Yale College in 1813. He was tutor at Yale and for ten years professor in the University of North Carolina. From 1825 to 1859 he held a professorship at Yale. In 1840 he was made a member of the Board of Commissioners of Common Schools in Connecticut. His educational writings include *State of Education in Connecticut*, *An Academy for Schoolmasters* (in which he outlined a scheme for a college for the training of teachers), and *Ideals of a Perfect Teacher*. His textbooks include *Natural Philosophy* (1831), *School Philosophy* (1832), *Astronomy* (1839), and *Rudiments of Natural Philosophy and Astronomy* (1842). Professor Olmsted was actively identified with the American Institute of Instruction and the American Association for the Advancement of Education (q.v.).

W. S. M.

OLNEY, JESSE (1798-1872).—Text-book author; was educated in the common schools. For several years he taught in the district schools of New York and later in the Hartford Grammar School. For ten years he was a member of the Connecticut legislature. He was the author of many schoolbooks, including geographies, readers, arithmetics, and histories. His common school geography passed through ninety-eight editions, and its sale is said to have been exceeded in its day only by Noah Webster's spelling book.

W. S. M.

OLYMPIC GAMES.—Probably growing out of very ancient local athletic festivals, the Olympic Games in Elis were the oldest and

greatest of the Panhellenic festivals. The nationalization of this festival is assigned traditionally to the year 776 B.C. The Greek era began with the Olympic games celebrated once in four years, and every period of four years was called an Olympiad. It was from the first under the charge of the Eleians, but they invited competitors from neighboring states, and the custom of attending the games spread to more distant cities. From an Eleian event, the festival became Peloponnesian and finally Panhellenic. Early in the sixth century, other festivals were established: the Pythian games, celebrated on the Krissean Plain; the Nemean games, held in the groves of Nemea; and the Isthmian games, which took place at Corinth. These festivals survived to the close of Greek history, but the Olympic games continued to be the most glorious until the end.

The original motive for these festivals was the glorification of the strong and agile body. Athletic contests always constituted the chief attractions, but the festivals served to bring together the greatest lyric poets, sages, statesmen, orators, artists, sculptors, and potters. These celebrations were great national holidays which served as pleasant occasions of reunion for congenial spirits and tended to the diffusion of national ideas.

According to a fairly reliable tradition there was originally, and for twelve following Olympiads, only one contest: the *stádios*, a foot race, consisting of a single lap of a *stadion* of 200 yards. Other races of two, seven, twelve, and perhaps twenty-four laps were added later. About the time of the eighteenth Olympiad, the wrestling match and the Pentathlon (q.v.) made their appearance. An athlete had to win at least three of the contests to be crowned victor of the Pentathlon. Boxing and the chariot race are said to have been added in the twenty-third Olympiad. The games gradually grew more and more elaborate, and the time over which they extended was increased from a single day to five or six.

The festival was conducted by about ten judges, elected by the people of Elis a year beforehand. The candidates for the various contests were required to present themselves for examination thirty days before the festival. Each candidate must prove himself to be of pure Hellenic stock, and must give evidence of having trained during ten months in a gymnasium. During the last thirty days before the festival, the candidates practiced in the gymnasium under the supervision of the judges. After an athlete had been entered for a contest, it was considered the greatest ignominy for him to withdraw for any reason; indeed, for so doing he was heavily fined. Eleven days before the festival, the judges caused to be proclaimed by heralds throughout all the cities of Hellas the truce, sacred

to Olympian Zeus, which was to last one month. It was this truce that made the Olympia possible as a Panhellenic institution, for during the thirty days' truce, all wars between Hellenic states were held in abeyance, and travelers were allowed to journey through them unmolested.

The athletic contests were conducted with much attention to details. In the foot races they were very particular that all should start at the same time and from the same line, and no fraud or trickery was permitted. It was also contrary to rule for an athlete to slacken his speed purposely to allow his fellow contestant to win. The foot races were run in heats of four, and the winners of each heat ran in the final race, in which the winner was crowned as victor. The victor in the running race at Olympia was regarded as an honor to his country, and gave his name to the current Olympiad, and on reaching home entered his native city to the notes of a triumphant song, written by a Pindar or Simonides. The last Olympiad was the 293d and ended in 394 A.D.

Modern Revival of Olympic Games.—After a lapse of more than 1500 years, the Olympic games were revived at Athens in 1896 under circumstances of interest to the modern educator. The motive behind the movement for the organization of the modern Olympic games was the interest of a French nobleman in educational reform. Baron Pierre de Coubertin, after leaving the *École des Sciences politiques* in 1883, spent some time in England studying the educational and social conditions in the public schools. He was profoundly impressed with the educational ideals of Thomas Arnold (*q.v.*) as described in *Tom Brown's Schooldays*, and exemplified in the English public schools. He appreciated the large educational value of athletic sports in the physical, social, and moral development of adolescent boys and resolved to devote himself to the task of securing similar educational advantages for his fellow countrymen.

Ten years of energetic and persistent effort brought only meager results. During this period De Coubertin introduced sports in a few schools and *lycées* in Paris, he organized athletic contests in connection with the Paris exposition of 1889, he made a tour to study physical education in American colleges, he organized an athletic union in France, and edited a magazine, the *Athletic Review*. He encountered much opposition and indifference in his efforts to popularize athletics in France. At a conference held at the Sorbonne in 1892, in connection with the jubilee of the French Athletic Union, Baron de Coubertin made an address on "Physical Exercises in Antiquity, the Middle Ages, and Modern Times," and advocated the revival of the Olympic games. With the coöperation of Professor William Milligan Sloane, then of

Princeton, and Mr. C. Herbert, secretary of the Amateur Athletic Union of England, he organized the Paris International Congress for the study and propagation of the principles of amateurism, to be held in June, 1894. The last paragraph of the circular letter announcing the Congress contained the following statement: "The revival of the Olympic games in accordance with modern life and conditions would bring together every four years representatives of the world's nations, and one is justified in the belief that these peaceful and courteous contests would constitute the best form of internationalism."

The congress voted to inaugurate the modern Olympic games in 1896 at Athens, if possible, and to hold the second Olympiad in connection with the Paris exposition of 1900. These plans were carried out successfully under the direction of an International Olympic Games Committee, with Baron de Coubertin as president. The Greeks entered into the spirit of the movement with great enthusiasm. Representatives were present from many nations to compete in the various contests in running, jumping, throwing the discus, javelin, and weights, swimming, gymnastics, wrestling, fencing, shooting, etc. The games aroused world-wide interest and resulted in a remarkable expansion of all forms of physical education in many countries, particularly in continental Europe. The Olympic games were held again in Paris, 1900; St. Louis, 1904; Athens, 1906; London, 1908; and Stockholm, 1912. The 1916 games are to be held in Berlin. The object of the founders of this great educational movement has been realized in a large measure.

OMAR KHAYYAM.—(Gi jāt ed-din, Abū'l-Fath, 'Omar ben Ibrāhīm el-Chaijām), the well-known author of the Persian poem, the *Rubāiyāt*, was better known to his own people as a writer of philosophical and mathematical works. He lived in eastern Persia in the eleventh century, and in 1074-1075 was making astronomical observations in Raj or Nishapur. He died at Nishapur about 1123-1124. Of his philosophical works, one on existence (*fi'l-vuḡūd*) is preserved in manuscript in Berlin. His algebra was published in Arabic and French by Woepeke (Paris, 1851). A work on the postulates of Euclid written by him is still extant in Leyden, and one on the mixture of metals is in Gotha, but neither has been published. A work at one time in Leyden, on difficult problems of arithmetic (*Mushkilāt al hisāb*), is apparently lost. The algebra

is one of the best works on the subject that appeared in the Arab-Persian ascendancy.

ONE-SESSION PERIOD. — See **SESSIONS**, **LENGTH OF**.

ONTARIO AGRICULTURE COLLEGE, GUELPH, CANADA. — The Ontario Agricultural College was established by the Provincial Government of Ontario in 1873. The annual grants have increased, until now about a quarter of a million dollars is spent each year on its upkeep, besides the cost of additional new buildings from time to time. The objects of the institution are to give instruction in the best methods of farming, and the best methods of housekeeping, including thorough practical instruction in cooking and sewing and laundry work for every girl, and optional courses in horticulture, poultry raising, bee keeping, and dairying.

Under these circumstances the entrance requirements have been kept very low, so far as general education is concerned. Male students may enter upon the course in agriculture without any preliminary training, except good farm practice. Most matriculants are, however, fairly well prepared in the ordinary studies of the public school. From this number, by examination each year, are selected those who will be permitted to go on with the work of the third and fourth years, and those accomplishing the term work and passing the prescribed examinations are at the end of the four years admitted to the degree of Bachelor of the Science of Agriculture from the University of Toronto (*q.v.*), with which institution this college is affiliated. A diploma is given at the end of the first two years for practical knowledge and scientific equipment in practical farm operations. During the winter months short courses are held in stock and seed judging, poultry raising, butter and cheese making, fruit growing, beekeeping, and domestic science. Courses also are provided in elementary agriculture and nature study to prepare the teachers of the Province to give agricultural courses in elementary schools. Agriculture might well be taught in the public schools in rural districts. Teachers, however, were unprepared, notwithstanding that good textbooks had been written on the subject by practical men. Practical courses for teachers have recently been established lasting ten weeks in the spring and again five weeks in the summer. At the present time there are students in attendance from twenty-two different countries.

ONTOGENY. — A term used to designate the whole course of individual development. It is contrasted with philogeny, which is used to designate the course of general evolution in the species or race. A certain parallelism exists between ontogeny and philogeny. (See **CULTURE EPOCHS THEORY**.) C. H. J.

OPEN-AIR SCHOOLS. — The open-air school is a type of special school developed in Europe and America for the education of physically debilitated children. It is designed to make it possible for such children to continue their education and at the same time to regain their health and vitality. To attain these ends the classes are held in the open air, the children are well fed and warmly clad, and the formal work in the school subjects is reduced and modified.

The first school of this type was opened in Charlottenburg, a suburb of Berlin, in the year 1904. It was designed to meet the needs of a group of backward and physically debilitated pupils who could not carry the work in the regular schools and were not so mentally deficient as to be fit subjects for classes for subnormal pupils. The purpose of this educational innovation is reflected in the name "Open-Air Recovery School" which was used to describe it and which is still commonly employed in Europe in referring to schools of this type. The distinguishing characteristics of the régime in this pioneer open-air school included an outdoor life and abundance of good food, strict cleanliness, suitable clothing, skilled teachers, small classes, and school work modified in kind and reduced in quantity. The children who were the fortunate subjects of this first open-air experiment made wonderful progress. They increased rapidly in weight and strength, and many who had been suffering from serious ailments were entirely cured. Moreover, it was found that although these children had spent less than half as much time on school-work as their companions in the regular schools, they had not fallen back in their studies.

The reports of these combined physical and mental benefits spread throughout Germany and caused the school authorities of other cities to begin the erection of open air schools. In less than three years the movement had spread to England, and in 1907 London opened its first school. The results obtained were as remarkable as those previously reported from Germany, and again popular enthusiasm was aroused, with the result that other towns and cities throughout Great Britain began to plan for similar establishments.

Meanwhile the movement had spread to America, where the credit of starting the first open-air school must be shared by New York and Providence. In 1904 the former city loaned the services of one of its public school teachers and supplied school material for the

OPEN-AIR SCHOOLS

children of an outdoor hospital for tuberculous children. The first American open-air school, as that term is now understood, was opened in January, 1908, in the city of Providence, R.I. The location was a room in an abandoned schoolhouse. This room was remodeled by converting the ordinary four-sided classroom into one of three sides, leaving one entire side open to the air. In this room the Providence authorities began in the dead of winter to teach a class of children variously termed anæmic and tuberculous. The children wore outdoor wraps, sat in warm sitting-out bags, and on cold days had warm soap-stones at their feet. They were well fed, and their school studies were reduced in quantity. They immediately began to improve both physically and mentally and made marked advances in their school work. Six months after Providence began work, an open-air school for tuberculous children was started in one of the parks of Boston, Mass. There were forty-one children in the school, and after the first summer's work it was found that there were twenty-three cases where the disease had either been arrested or entirely cured. Five months later, in December, 1908, a new school was opened in New York City on an abandoned ferryboat. Chicago began work in the summer of 1909 in a camp in one of the school yards and later continued the work on the roof of a building in the heart of the city.

From these early beginnings the movement for open-air schools has rapidly spread in Germany, England, and America and has made considerable progress in France. In all these countries it is recognized that the open-air school has passed the experimental stage. In Germany it has become an integral part of the elementary school system. Among the municipalities having the new schools may be mentioned Mulhausen, Munchen-Gladbach, Elberfeld, Lubeck, Berlin, Solingen, Cologne, and Aix, and there can be little doubt that within a few years the majority of the large industrial towns will have schools of this type. In general, German schools are modeled after the pioneer school at Charlottenburg. In all cases the principal characteristics are open-air treatment, plenty of good food, warm clothing, strict cleanliness, and expert medical and dental attention. The keynote of the schoolwork is constant change from work to play, reading, singing, and rest, together with constant stimulation of interest.

The record of progress in England is similar to that of Germany. Schools of the new type have been established in the suburbs of London, Manchester, Bradford, Halifax, and other industrial cities. In France open-air schools are being established in many cities, generally as developments of the "school colonies," which have for years furnished vacations in country places to city children.

OPEN-AIR SCHOOLS

Records of the actual opening of schools of the new type in other countries are as yet lacking, but preparations for establishing them have been made in Scotland, Austria, Italy, Canada, Mexico, and Japan.

The open-air schools in other countries differ from most of those established in the United States in the class of children cared for. In the United States these schools are in general designed for the care of children suffering from tuberculosis in its incipient stages. They are essentially therapeutic agencies for the care of a special class of sick children. In Europe the aim is in general distinctly broader, and the schools receive as pupils children suffering from various forms of physical debility and subnormal vitality.

Popular interest and enthusiasm have been aroused by the success of the open-air schools in America to a degree which has seldom if ever been equaled by that shown for any other educational innovation. This has been stimulated by the unbroken record of success of the early schools. No single case of failure has yet been recorded, and no city that has undertaken the work has subsequently abandoned it. The rapidity with which the movement has spread is indicated by the following figures, showing the number of cities in the United States having open-air schools in each school year from the opening of the Providence school in 1908 to January, 1912:—

SCHOOL YEAR	NUMBER OF CITIES HAVING OPEN-AIR SCHOOLS
1907-1908	3
1908-1909	7
1909-1910	15
1910-1911	32
1911-1912	44

Daily Program.—The daily programs differ in detail only in the different countries and cities. The following time-table, showing the procedure in an open-air school in New York City, may be considered typical of these programs:—

8 45 to 9 00	Arrive at school, get warm.
9 00 to 9 30	Fed with egg and large glassful of milk. Rest outdoors in sleeping blankets.
9 30 to 10 30	Schoolwork.
10 30 to 10 45	Short recess, feeding with milk and bread.
10 45 to 11 30	Schoolwork.
11 30 to 12 00	Recess, go to wash room and prepare for dinner.
12 00 to 12 30	Dinner.
12 30 to 2 00	Rest in bed, encouraged to sleep.
2 00 to 3 00	Schoolwork.
3 00 to 3 15	Short recess, feeding of milk and bread.
3 15 to 4 00	Schoolwork.
4 00 to 5 00	School dismissed, play an hour.
5 00	Go home.

Clothing.—Experience has conclusively demonstrated that, if children are to be benefited by the open-air treatment, they must be kept warm. This can only be accomplished during cold weather by providing them with sufficient clothing of the right sort. If they do not

OPEN-AIR SCHOOLS

possess good wool underwear and warm, well-fitting outer garments, these must be supplied directly by the school or indirectly by some charitable agency. It is absolutely essential in cold climates that each child be provided with a heavy overcoat, sitting-out bag, two blankets, a wool cap, and warm gloves. In several cities the children are provided with Eskimo suits, which are made of heavy blanketing and put on over the regular house clothes. These suits have proved most satisfactory for the purpose and are unusually attractive in appearance. Extra shoes and stockings must be available to be substituted in case of need for those worn by children who come to school with wet feet. The most satisfactory outer foot covering for this purpose is the heavy wool felt boot reaching nearly to the knee. Wooden foot boxes, measuring about two feet long by a foot and a half wide and a foot high, and lined with quilting, are useful for keeping the children's feet warm when the temperature is low. The sitting-out bags are made of heavy blanketing covered with canvas and may be purchased from dealers in sanatorium equipment. They are cut and stitched so as to conform to the shape of the chair and may be attached to it by tape at different points to prevent the child in the bag from slipping off.

Food.—Only less important than warm clothing in securing successful results is wholesome and adequate food. In general practice does not differ widely from that developed in the original Charlottenburg school, where the daily routine is as follows: The children arrive at about a quarter before eight and receive a bowl of soup and a slice of bread and butter. Classes commence at eight with an interval of five minutes after each half hour's instruction. At ten o'clock the children receive one or two glasses of milk and another slice of bread and butter. Dinner is served at half past twelve and consists of about three ounces of meat, vegetables, and soup. After dinner the children rest or sleep for two hours. At four o'clock milk, rye bread, and jam are given. The last meal consists of soup and bread and butter and is given at a quarter before seven, after which the children return home. The expenditure for the feeding amounts to about twelve cents per day per child. Poor children are excused from paying, and the others pay in full or in part, according to the circumstances of their parents. American practice differs little from that described, except that the school day is shorter and hence the meals given are frequently reduced in number.

In addition to the meals taken at the school, the children have milk and bread, or cereal and milk, or sometimes an egg before leaving home in the morning, and again a light meal on their return home at night. This brings the total fuel value of the food eaten during

OPEN-AIR SCHOOLS

the day up to about 3000 calories, which is probably high for a normal child, but not for these tuberculous children. The cost of feeding in America varies from about sixteen cents to about twenty-five cents per child per day.

Administration.—In most American cities the open-air schools are administered by a partnership of responsibility. In the majority of cases the Board of Education meets the cost for teachers' salaries, school premises, and schoolroom equipment, while the expense for food and clothing is defrayed by hospitals, charitable organizations, and societies for the prevention and cure of tuberculosis. At the close of the school year 1910-1911 data as to the administration of forty-seven open-air schools in different American cities were as follows:—

Board of education and tuberculosis association	20
Board of education and private association	11
Board of education only	7
Board of education and other city department	6
Tuberculosis association only	2
Board of education and private fund	1
	<u>47</u>

The premises occupied by the schools were as varied as the forms of administration. Among thirty-nine schools the following variations were found:—

Remodeled rooms	14
Special buildings	6
Roofs	6
Regular classrooms with open windows	5
Boats	5
Tents	2
Barn	1
	<u>39</u>

Expense.—The expense of conducting open-air schools depends in very large degree on local conditions. The only certainty is that the cost will always be greater than that of the ordinary class. The first reason for the added cost is that there are only about half as many children per teacher, the desirable limit being about twenty. In the second place the expense for food amounts to from sixteen to twenty-five cents per child per day. In the third place there is the individual equipment of each child, which is necessarily expensive. Its items with their cost are about as follows:—

Blanket	\$5.00
Eskimo suit	3.50
Sitting-out bag	3.00
Cot	1.75
Felt boots50
Mittens40
Thermometer25
Toothbrush20
	<u>\$14.60</u>

This individual equipment is in the nature of permanent investment, and can be used with slight replacement for several years. Taking all of these different added expenses into account, it is fair to say that the education of a child in an open-air school costs nearly three times as much as does the education of the same child in the ordinary school.

OPEN-AIR SCHOOLS.

OPEN-AIR SCHOOLS

The Need for Open-air Schools.—There seems to be little question that the open-air recovery school is the most efficient agency yet devised for carrying on the instruction of physically debilitated children and at the same time curing them or ameliorating the ailments from which they suffer. The best available data seem to indicate that the children who are in need of such treatment as that afforded by the open-air school constitute from 3 to 5 per cent of the daily membership in the average city school system. It would probably not be far out of the way to say that of these at least one third, or from 1 to 2 per cent of all, are either definitely suffering from tuberculosis or are "pretuberculous."

Summary.—The open-air school is a combination of sanatorium, playground, and schoolroom, in which the daily régime has been characterized as consisting of double rations of air, double rations of food, and half rations of work. There are eight requisites, of which the first three are imperatively essential: (1) abundance of pure air; (2) plenty of good food, and (3) sufficient warm clothing; (4) shelter from the wind, for experience teaches nothing more clearly than that it is wind and not low temperature that causes suffering from cold; (5) shelter or refuge where the children can be taken during very inclement weather, and where any child who gets chilly during the session may at once go to get warm; (6) provision for sleeping after the noonday meal. For this purpose short folding cots are much more satisfactory than the steamer chairs ordinarily used; (7) the services of a skillful doctor and a competent nurse. These do not, of course, have to be in attendance continuously, but should be available. Finally, it is essential to have in charge a teacher who is intelligent, able, and familiar with the methods and aims of the outdoor treatment.

OPENING EXERCISE.—It is usual to allot a short period of time to the formal opening of school or class work. The period allotted is from ten to twenty minutes. The exercises vary greatly in content and form; in the morning exercises of a school, announcements of general interest are made and matters of routine adjusted, readings and short addresses occupying the remainder of the time. This period is more largely in the hands of the pupils where the opening exercises are those of a single classroom. The opening exercise is important in starting the day's work with the requisite attitude. It is a valuable device in establishing and maintaining the group spirit of the class or school.

OPERATION.—See SYMBOLS OF OPERATION.

OPHTHALMIA NEONATORUM.—Purulent conjunctivitis, or inflammation of the eyes of new-born babies, is a specific germ disease, caused usually by a gonorrheal infection from the tissues of the mother during birth or from the careless use of towels, etc., later. The inflammation commonly appears on the third or fourth day, may be mistaken at first for mild conjunctivitis, but rapidly develops acute symptoms. If unchecked, it often leads to incurable blindness of one or both eyes, or marked impairment of vision through corneal scars. Estimates credit this malady as the cause of 50 per cent of the blindness in nurseries for blind babies, 25 per cent of the blindness in blind schools, and 10 per cent of the blindness in the United States. It is, then, the largest single cause of blindness. New York State health officials believe that, in 1910, the inflammation appeared in about one birth in a hundred.

Ophthalmia neonatorum may be prevented by washing the infant's eyes in sterile water after the head is born and by dropping two drops of 1 to 2 per cent solution of nitrate of silver directly upon the eyeball as soon after birth as possible. Even if the inflammation does appear, proper treatment will usually avert serious consequences, but the treatment must be prompt and be supplemented by careful nursing for several weeks, preferably in a hospital.

That so many cases of blindness occur, despite the simplicity of prophylaxis, is due to the ignorance of parents, midwives, and even of some physicians, of the source, the virulence, and the danger of the infection. To combat this ignorance, the American Medical Association has long maintained a committee on prevention of blindness, while the health departments and charitable organizations of the more progressive states have instituted

vigorous "lay campaigns" of information. In New York and Massachusetts the disease is among those reportable to the health authorities. G. M. W.

OPINION.—A term given to beliefs of a peculiarly personal or individual character, and to beliefs which, though generally current, lack scientific warrant, having their ground in custom rather than in evidence. (The term public opinion is used to denote the beliefs characteristic of a community in so far as these beliefs influence corporate or public action.) One of the objects of education is to produce the habit of mind which discriminates between opinion and grounded conviction, and which prevents opinions being held and asserted dogmatically. Plato among ancient educationalists and Locke among modern have especially insisted upon the harmfulness of confusing opinions and knowledge, and the importance of devising educational methods to safeguard the mind against this danger.

OPTIMISM.—The origin of the conception of optimism throws much light upon its nature. Plato had made the Idea of the Good the central principle of his metaphysics and of his dialectic. He had, however, admitted

a passive principle in the constitution of the world sometimes called Matter, sometimes Non-being, sometimes The Other, which was capable of hindering the realization of this Good. Aristotle (*q.v.*) conceived of matter as the potentiality of a process through which ends as complete actualities are realized and thus did away with the Platonic dualism in that form. But in teaching that Nature always acts for the good, or for a final cause, he also admitted a principle of chance in things which was capable of preventing in particular cases the realization of the true end or Good. Aristotle's philosophy might thus be called an optimism upon the whole, tempered by the acknowledgment of unavoidable accidents in details. The Neoplatonists accounted for matter, resistance, and multiplicity by the idea of a series of emanations of which matter was the lowest. Its far remove from The One Good accounted for its appearance of evil. But even this appearance of evil was due to judging from only a partial standpoint; seen in its place in the whole, matter would be apprehended as contributing to its perfection.

St. Augustine (*q.v.*) adapted these conceptions to the needs of Christian apologetic. The conception of God as Creator compelled him to reject the idea that there is any principle of evil in matter or in the created cosmos at any point. Things that may seem evil to our finite judgment would be seen to enhance the goodness of the whole, could we but perceive from that standpoint. Real evil exists, however, but not cosmologically or metaphysically; it is due to the will of man in disobeying the divine command and substituting his will for the divine will. Even with respect to this, however, St. Augustine was so impressed with the sovereignty of the divine will and power, which must be absolutely good, that even sin was, metaphysically considered, privative rather than a positive reality. Through this influence of the great Father of the Church, optimism became an official part of Christian philosophy.

In the seventeenth century, Leibnitz in his *Théodicée* attempted, in terms of his philosophy of monads and their preestablished harmony, a purely rationalistic proof that this is the best of all possible worlds. Modern optimistic theories, outside of professedly theological circles, really date from Leibnitz. Voltaire, instigated by the destructiveness of the Lisbon earthquake, ridiculed the fashionable Leibnitzian optimism in his poem, *Candide*. However, optimism was in the air in the eighteenth century, being congenial to rationalistic deism and to the beliefs of the social reformers in the indefinite perfectibility of man. (See CONDORCÉ.) Even Rousseau, with his anti-rationalistic tendencies, taught the original goodness of nature and of man, attributing evil to the influence of institutions in destroying equal liberty.

A contemporary of Leibnitz, the Dutch Jew Spinoza, had dealt to the metaphysical basis of optimism the most severe blow that it could have possibly received. He taught that Nature is what it must be by an absolute logical necessity and that considerations of good and evil alike are equally foreign to its nature. They are relative only to man with his desires. Spinoza's teaching had no influence for over a century. Finally the growth of mechanical science and of dislike for the doctrine of final causes in any form in connection with nature prepared the way for a general acceptance of the essentials of Spinoza's view. This change shifted the problem from the question whether the world, or Being, metaphysically considered, is good to the question whether Life, empirically considered, is a good; or in its popular statement whether "Life is worth living." The most marked tendency of recent discussion is the development of the conception of "Meliorism," the idea that at least there is a sufficient basis of goodness in life and its conditions so that by thought and earnest effort we may constantly make better things. This conception attacks optimism on the ground that it encourages a fatalistic contentment with things as they are; what is needed is the frank recognition of evils, not for the sake of accepting them as final, but for the sake of arousing energy to remedy them. The conception of progress practically takes the place of the old notion of the metaphysical Good. J. D.

ORAL ARITHMETIC.—See MENTAL ARITHMETIC; PESTALOZZI.

ORAL ENGLISH.—See COMPOSITION.

ORAL METHODS.—There are three characteristic modes by which the school can provide the child with experience and knowledge; one direct and the other two indirect: (1) The school may provide the child with direct sense impressions through objective teaching (*q.v.*). (2) It may convey the experiences of teachers and fellow pupils to the child through an oral presentation. (3) It may teach the child to read the recorded knowledge of the men and women with whom he has not had and cannot have personal contact. Traditionally, the second method of instruction has always held the central place in school-teaching. Even what teachers and children read, they finally convey to each other orally in the classroom. The name "recitation" applied to the class exercise implies the dominantly oral nature of school methods of teaching and learning. This dominance of oral teaching still holds true. Instruction through

the use of objective teaching and other modes of giving direct sense impressions is not an old tradition in the schools. The difficulties of its use necessarily limit its employment. The still more recent movement toward teaching children how to study the written text in the independent pursuit of knowledge has not yet assumed a large place in the schools, though texts as a basis for oral discussion in class have always had a very important place.

All oral teaching has the advantage that it is rapid and subject to easy control by the teacher. Its weaknesses are that it tends to degenerate into mere verbalism and to allow the teacher's activities to dominate the teaching situation completely. Thus the teacher does most of the talking in the school, and the children are too often merely receptive. Again, children pronounce words glibly in reading without the real thought of what they read, and teachers frequently accept verbal definitions rather than actual applications of meanings.

ORATORY. — See ORATIONS, SCHOOL; DECLAMATION; DEBATING; and for the historical place of Oratory in Education see ROMAN EDUCATION; RENAISSANCE AND EDUCATION.

ORATORY, FRENCH CONGREGATION OF THE — An order founded in France in 1611 by Cardinal Pierre de Bérulle, in imitation of the Congregation of the Oratory founded in 1575 by St. Philip Neri (1515-1595) in Italy. The Congregation consisted of priests, not monks, bound by no other vow than that of the priesthood. While not intended to undertake the education of any but priests, the French Oratorians were soon in charge of a number of colleges and seminaries not only in France, but in Spain and the Netherlands. In 1711 the education of boys was recognized as one of their special functions. Their chief colleges were at Dieppe, Mans, and Juilly, the last of which became the chief and model college. Besides colleges, including secondary departments, military schools, seminaries, and houses of study were maintained. The characteristic features of the Congregation were the absence of that militant and political spirit which marked the Jesuits, and an emphasis on liberal and Christian education. The liberal arts and humanities were not neglected, nor on the other side were the sciences despised. The close connection of many members of the Congregation with Cartesianism insured the introduction of science into the curriculum. The second superior, P. de Condren, drew up a *Ratio Studiorum* (1634) which was edited by P. Morin as the *Ratio Studiorum a magistris et professoribus Congregationis Oratorii Domini*

Jesu observanda (1645). Later educational works were the *Entretiens sur les Sciences* (1683) of P. Lamy and *Méthodes d'étudier et d'enseigner* (1681) of P. Thomassin.

The chief educational contribution of the Oratorians, who in many respects come close to the Port Royalists, were: (1) The introduction of the vernacular and the exclusion of Latin until the fourth form. (2) The teaching of history, for which there was a chair in all their schools. This subject was taught in the vernacular throughout, and French history was taken up before the classical. Geography was taught in close connection with history. (3) New methods were employed in teaching the classics, Latin receiving more attention than Greek. Grammar was taught by the aid of the vernacular and oral expression was given greater emphasis than written themes. (4) Physics and chemistry had a place in the curriculum of some schools of the Oratorians. (5) In philosophy, as has already been observed, Cartesian influences were marked. In addition to the ordinary school subjects there were taught at Juilly ornamental arts, horse riding, music, and dancing. (See ACADÉMIES, COURTY.) Discipline in the school was gentle. The same professor took a class through from the first form to the class of philosophy, a practice which largely eliminated the question of discipline. To a certain extent the Oratorians employed the monitorial system, decurions being appointed to hear lessons under the supervision of a prefect of studies. The individual abilities were considered, and a certain amount of independence and freedom in studies was permitted under direction and supervision. Among distinguished members of the Congregation may be mentioned the teachers and philosophers, Lamy and Thomassin; preachers Mascaron and Massillon; exegetes Richard Simon and Duguet; the philosopher Malebranche (*q.v.*); and the statesman Daunou (*q.v.*). The Congregation was practically dissolved during the days of the Revolution. It was reconstituted in 1852 as the Oratory of the Immaculate Conception.

In England Cardinal Newman (*q.v.*) founded in 1847 an Oratory of St. Philip Neri, at Edgbaston since 1854. Several schools, two in Birmingham, have been established under the government of Fathers of the Congregation of the Oratory.

OREGON AGRICULTURAL COLLEGE, CORVALLIS, ORE. — A land-grant college founded in pursuance of the Act of 1862. As there was no state institution in existence, the legislature from 1860 to 1885 made annual appropriations to Corvallis College, then under the control of the Methodist Episcopal Church, South. In 1885 the college became a state institution, the citizens of Benton County providing a central building. The college owns 360 acres of land and thirty buildings. Secondary and degree courses are offered, two years of high school work being required for entrance to the latter. Degree courses are given in the following branches: agriculture, forestry, domestic science and art, engineering, commerce, and pharmacy. Two-year secondary courses and short courses are also conducted. In 1911-1912 there was a total enrollment of 2868 students in all departments. The faculty consists of about 150 members.

OREGON, STATE OF. — A state in the Pacific northwest, carved from the original Oregon Territory, and confirmed to the United States in 1846 by the treaty with Great Britain. In 1848 the Territory of Oregon was organized by Congress; in 1853 Washington Territory was separated from it, and in 1859 Oregon was admitted to the Union as the thirty-third state. The state has a land area of 95,607 square miles, which is about the same size as New York and Pennsylvania combined, and three fourths the size of the state of Prussia. For administrative purposes the state is divided into thirty-four counties, and these in turn into three classes of school districts. In 1910 Oregon had a total population of 672,765, and a density of population of 7.0 persons per square mile. Omitting the city of Portland, which contains one third

of the population of the state, the average density is only 4.9 per square mile.

Educational History. — First discovered in 1792 and first partially explored in 1805-1806; settlement did not begin until about 1835, but was relatively rapid after 1843. The first settlers were Hudson Bay Company employes, and private or mission schools supplied the needs of the few children at the trading posts. Beginning in 1834, the Methodist Episcopal Church began to found mission schools in the Territory, and they were joined by the American Board of Commissioners for Foreign Missions in 1836, by the Roman Catholics in 1841, by the Congregationalists in 1847, and by the Protestant Episcopal Church in 1869. When the first provisional government was established in 1845, it was declared that "schools and the means of education should be encouraged," but no funds to maintain a school were available, except subscriptions and mission appropriations. The first territorial legislature, in 1849, enacted the first school law for the Territory. This law appropriated the income from the school lands, together with all fines, forfeitures, and licenses, and the proceeds of a two-mill territorial tax to the support of common schools. This income was to be distributed among the school districts in existence on the basis of their school census. The law further provided for the organization of schools on the district system plan; the election annually of three directors to employ teachers, and to establish and care for the schools; the appointment of a county board of examiners of three, to examine and certificate teachers; the election of a county school commissioner in each county, to look after the interests of the schools; and for the choice by the legislature of a Territorial Superintendent of Common Schools, to supervise the educational system of the state. School directors were to hold office for one year, all other school officers for three years. In 1851, however, the state school tax was cut in half (restored to two mills in 1855), and the office of Territorial Superintendent was abolished. In 1855 the title of the county school officers was changed to county superintendent of schools; district school directors were empowered, on vote of the district school meeting, to levy a district school tax; teachers were first required to keep a school register, and to file it with the district clerk; district reports were required, or an appropriation of funds was refused; and schools receiving public funds were declared free to all children four to twenty-one years of age. For many years after this date, however, the rate bill (*q. v.*) was resorted to in order to prolong the term.

In 1857 a constitution was formed, and upon this the Territory entered the Union in 1859. This provided that all school-section land, the 500,000-acre grant to new states, and the

5 per cent fund (see NATIONAL GOVERNMENT AND EDUCATION) should be a sacred trust fund for common schools; that the lands given for a university should form a trust fund for that purpose; that for five years at least the Governor should act, *ex officio*, as State Superintendent of Public Instruction; that a county superintendent should be elected, for two-year terms, in each county; religious control and sectarian aid were forbidden; the legislature was directed to establish a uniform public school system and schools of higher grade, with a free school in every district for at least three months each year; the establishment of a state university with normal and agricultural departments was directed; and a Board of Commissioners, consisting of the Governor, the Secretary of State, and State Treasurer, was created to manage the school lands and school funds. In 1872, the five years having expired, the legislature elected a State Superintendent of Schools, detaching the office from that of Governor, and provided for the election of a Superintendent by the people in 1874, and every four years thereafter. This created the first unification of the schools under the new state organization, there having been practically as many school systems before as there were counties in the state. The same legislature further revised the school law and provided for a State Board of Education, to consist of the Governor, Secretary of State, and State Superintendent, this Board to have power to authorize a series of textbooks for the schools, and to adopt rules and regulations for their government. The State Board was also made, *ex officio*, a State Board of Examination, for the granting of state certificates and life diplomas. County superintendents were given enlarged functions, and the county school tax, previously authorized, was increased from two to three mills. Teachers' institutes were begun, the State Superintendent being authorized to hold one every year in each judicial district of the state. The state university was also founded in 1872 and located at Eugene, but it was not opened for instruction until 1876. At that time there were but twenty-two organized counties and but 642 school districts in the state.

The work of the State Superintendents for the next fifteen years consisted almost entirely in general supervision, in the developing and perfecting of statistical information, and in the organization of the teachers' institute work. The power given to the State Board of Education to make rules and regulations having the force of law was used to shape the slowly developing school system. Little school legislation of importance was enacted between 1872 and 1899. In 1874 a school for the blind was organized; in 1883 the normal school at Monmouth was placed under state control; and in 1885 the normal school at Weston was

similarly accepted and given a small appropriation; in 1885 a separate agricultural and mechanical college was established at Corvallis, and the Department of Public Instruction was given the power to decide appeals on school law points; in 1887 the certification law was amended and strengthened, but in 1889 further amendments somewhat weakened the law; in 1889 an Arbor Day law and a defective compulsory education law were enacted; the State Teachers' Reading Circle was organized; a textbook law was enacted, under which the county superintendents were created an advisory body to adopt a series of uniform textbooks for the state; and the Oregon State Reform School at Salem was established; and in 1893 the textbook law was amended by adding the State Board of Education and the State Board of Examiners to the county superintendents, as the adopting body.

Beginning in 1899, a series of new and important laws began to be enacted, and the educational situation has been greatly changed and improved since that time. In 1899 the certification law was revised and strengthened, training in normal schools was recognized for certification, and the granting of state diplomas on mere experience was discontinued; a State Textbook Commission was created to take the place of the large and unwieldy body for the adoption of textbooks; the private normal schools at Ashland and Drain were accepted as additional state normal schools; a state course of study for the elementary schools, and examinations for graduation from the eighth grade were formulated by the State Board of Education; and the term of county superintendents was extended to four years, and educational qualifications were set up for the office. In 1901 a new revision of the school law was made, and the county high school law was enacted. In 1903 the consolidation of schools was permitted. In 1905 the "Pierce-Eddy law" requiring the county courts in every county to levy an annual county school tax of not less than \$6 per school census child, four to twenty years of age, in place of the former five-mill tax, was passed, and this has materially aided in the development of better schools. In 1907 a revised course of study for elementary and high schools was issued; the high schools were classified; a school library law was passed; a State Library Commission was created; the compulsory education law was revised and strengthened, and provision made for truant officers; the minimum school term was raised from three to four months; an annual convention of district school officers by counties, and an annual convention of county superintendents, were provided for; the required county school tax was raised from \$6 to \$7 per capita; a school-house flag law and a union school law were enacted; and a state institution for the feeble-

mined was established. In 1909 county high school funds for tuition purposes were made possible; special certificates for high school teachers were required; the minimum school term was raised from four to six months; a new county school fund apportionment bill, providing for a minimum apportionment of \$300 to each district was enacted; trustees were permitted to let schoolhouses for neighborhood gatherings; and a State Board of Higher Curricula, to unify the work of the State University and the State Agricultural College, was created. The legislature of 1909 also withdrew all aid from all of the normal schools of the state. Later, the matter of establishing one state normal school in place of the four was referred to the people and approved, and the legislature of 1911 created such a school and located it at Monmouth. The legislature of 1911 also abolished county teachers' certificates, and provided that all teachers' certificates should in the future be issued by the State Superintendent; provided for the recognition for teachers' certificates of graduation from standard normal schools and colleges; provided for teachers' training classes in four-year high schools; provided for additional county supervision in all counties having over sixty school districts; raised the county school tax from \$7 to \$8 per capita; provided for retirement funds for teachers in cities having over 10,000 school census children; and amended the union high school, the compulsory education, and the institute laws.

Present School System — At the head of the school system of Oregon, as thus evolved, is a State Superintendent of Public Instruction, assisted by a number of state boards for special purposes. The Superintendent is elected by the people for four-year terms, and receives a salary of \$3000 a year with \$900 additional for traveling expenses. He is charged with the general supervision of the county and district school officers, and the general oversight of the school system of the state. He is required to visit each county annually, to attend the county institutes, and to inspect the schools. He may visit and inspect all chartered institutions. He furnishes all blanks used, collects and compiles statistics, edits the school laws, and prepares and submits a biennial report to the legislature. He holds an annual convention of the county superintendents of the state and an annual teachers' association meeting, and prepares and issues the State Teachers' Reading Circle course. He decides all appeals on school matters submitted to him, and may submit the decision to the State Board of Education if he sees fit. He issues all teachers' certificates for the state, on report of the State Board of Examiners, of which he is the official head; may issue special certificates in special subjects as he sees fit; and acts as Secretary of the State Board of

Education, of which he is a member. He is also a member of the board for the standardization of normal schools and colleges, and of the Oregon Library Commission.

Oregon has a large number of state educational boards, each looking after some part of the state's educational system. The Standardization Board consists of the State Superintendent, the presidents of the State University, the Agricultural College, and the Normal School, the city superintendent of Portland, one member selected by the Independent College Presidents' Association, and one by the Catholic Educational Association of Oregon. Its purpose is to prepare lists of colleges and normal schools to be accepted as standard institutions for teachers' certificates. On the preparation of such a list by the U. S. Bureau of Education, the functions of this Board cease. The State Superintendent appoints the State Board of Examiners. This consists of nine professional teachers, who prepare the questions used, and such a number as is necessary to grade the answer papers. These two bodies constitute the State Board of Examiners, and the term of appointment is for two years. The State Superintendent is also authorized to appoint such clerical assistance as is necessary. The State Board of Education consists of the Governor, the Secretary of State, and the Superintendent of Public Instruction. Its chief power is the ability to make rules and regulations for the maintenance and discipline of the public schools of the state. It also approves of the adoptions made by the Textbook Commission, and promulgates the same; indicates the sources from which the questions on the theory and practice of teaching, in the examination of teachers, will be made up; and prescribes the course of study for the grammar, and first two high school grades of the public schools. The State Textbook Commission, appointed by the Governor, consists of five qualified persons, appointed for four-year terms. They advertise, examine the books submitted, and meet and select textbooks, for six-year periods, and submit the result of their labors to the State Board of Education for its approval. The Oregon Library Commission consists of the Governor, the State Superintendent, the President of the State University, the Librarian of the Library Association of Portland, and one person appointed, for a five-year term, by the Governor. The work of the board is to advise schools, libraries, associations, and communities as to the formation of libraries, and the purchase of library books; to purchase and operate traveling libraries; to conduct a summer library school; to prepare annual lists of suitable books for purchase; and to make rules and regulations as to library management. The Governor, the Secretary of State, and the State Treasurer constitute the State School-

Land Board, for the care of the school and university lands, and the proper investment of the income.

For each county there is a county superintendent of schools, elected by the people for four-year terms. Each must have had nine months' experience as a teacher, and must hold a first-grade teacher's certificate. The salary varies from \$400 to \$1800 a year, with \$200 for traveling expenses. Each has general supervision of the schools of his county, must visit each at least once each year, and is authorized to secure the care and protection of the school property of the county. He apportions the school funds to the districts, requires monthly reports from the teachers and an annual report from the district officers, and makes an annual report to the State Superintendent. He also hears and determines all appeals on disputed school questions; keeps a record of all contracts; consults with the district directors with reference to schoolhouse plans, and must approve all building plans for third-class districts; holds an annual county teachers' institute; and may hold an annual convention of district school officers. He grants a diploma of graduation to all who pass the state eighth-grade examination, and may appoint four others to assist him, known as a county board of examiners, in grading the answer papers. For each county there is a district boundary board, consisting of the county superintendent and the county commissioners (county court, if no commissioners exist), which meets to consider all proposed changes in district boundary lines. This board may also condemn land for schoolhouse purposes, and appoint truant officers for the second and third class school districts of the county. For each county having sixty or more school districts, districts of the first class under superintendents excepted, the county superintendent must appoint four persons, for four-year terms, who, together with the superintendent, constitute a county educational board. It is the work of this board to divide the county into supervision districts, consisting of not less than twenty nor more than fifty school districts, and to employ supervisors for each of these supervisory districts, except one, at salaries of from \$1000 to \$1200 and traveling expenses, for ten months' work. The county superintendent is designated as supervisor of one district. The county board acts as an advisory board to the county superintendent, and the district superintendents act under his direction and in his stead. Each supervisor must have had nine months' experience in teaching in the state, and must hold a state teacher's certificate.

Each county is divided by the district boundary board into a sufficient number of school districts, and these are divided into three classes. Districts having over 1000

children (cities) of school census age (four to twenty) are known as districts of the first class, and as such are given some important additional privileges; districts having from 200 to 1000 school census children (villages) are known as districts of the second class; and districts having less than 200 census children are known as districts of the third class. In second and third class districts, a district school board of three members is elected, one each year, for three-year terms, while in first-class districts, a board of five directors is elected, one each year, for five-year terms. Each board has a clerk, who exercises important functions. He is appointed by the board in first-class districts, and elected by the people in second and third class districts. The elections in all cases take place in June, and women may vote and hold office in school affairs. The annual meeting exists in second and third class districts, in a very modified form, its chief functions being the election of school officers (by ballot) and the voting of special taxes. The district clerk acts as secretary of the district boards, takes the school census, and preserves all records. He also has the custody of the district funds, and pays all orders drawn on the district, giving bonds for the safety of the funds in his charge. In first-class districts he exercises very important functions. Each board employs and contracts with its teachers, and may dismiss them for cause; has control of the school in all matters, except those relating to the course of study; may admit and exclude pupils; may loan textbooks to indigents; may furnish transportation, and may close the school and contract with another district to educate the children, when authorized by the voters to do so. In first and second class districts kindergartens may be established; first-class districts appoint their own attendance officers, and second-class districts may be permitted to do so, in second class districts the clerk may be appointed by the district board, if the district so votes; and in first-class districts the board may employ a city superintendent, prescribe the course of study and all rules and regulations, choose additional textbooks, create a city board of examination, provide evening schools and instruction in the modern languages, and may lease, build, and sell school property as it deems wise, and may contract indebtedness up to \$100,000.

School Support. — When Oregon was organized as a territory in 1848, Congress directed that section 36, in addition to the usual grant of section 16, be reserved for the aid of common schools. On entering the Union, Oregon received two sections in each township, a total of 3,329,706 acres. The 5 per cent fund, the grant of 500,000 acres of land to new states, the swamp land grants (see NATIONAL GOVERNMENT AND EDUCATION), and the ten sections of the capitol building

lands granted in 1859 were all added to the common school fund. The total fund is now nearly six millions of dollars, with 500,000 acres of land still on hand and not under lease. The income from this fund is small, and is apportioned to the counties and districts solely on the school census. No state tax is levied, the Oregon school system being financially a series of county school systems. The county court of each county must levy a county school tax equal to \$8 per census child (four to twenty) in the county, and districts must levy a special district tax of at least five mills. The state and county fund is apportioned to the districts on the combined basis of \$100 to each district as such, \$5 for each teacher in the district who attended a teachers' institute the preceding year, and the balance on school census. If this apportionment, together with the five-mill district tax, does not equal \$300, then the county must add enough from general county funds to raise it to this amount. High schools must be supported separately, unless an eight months' elementary school has first been maintained. Special county high school, high school tuition, and library taxes are levied, in addition to any needed county tax to provide \$300 per year in every school district.

Teachers and Training. — The state employs about 4000 teachers, outside of the city of Portland, which employs about 750 more. For the training of future teachers, the state now maintains one normal school, at Monmouth. The high school training-class system has recently been introduced. All teachers' certificates are issued by the State Superintendent, and are valid anywhere in the state, except city certificates and temporary county permits. Any city of over 100,000 population (Portland) may appoint a city examining board and grant its own certificates, but state certificates must be accepted by the city, while city certificates are not valid elsewhere. Five kinds of state certificates are issued, — life, five-year state, five-year primary, one-year, and special certificates. The one-year certificates are renewable once; the others more than once. Graduates of high school training classes receive one-year certificates, and graduates of standard colleges and normal schools are granted certificates, if they have met the required conditions. All future high school teachers must be college graduates. A state teachers' reading circle, under the direction of the State Superintendent, has been organized recently, and no teacher (except in first-class districts) can have his or her certificate registered (by county superintendents) for the following year, who has not done the required reading. Any city having 10,000 school children may create a teachers' retirement fund, to which 1 per cent of the district's share of the county school tax is added annually.

Educational Conditions. — Oregon is essentially a rural and an agricultural state. Outside of the city of Portland, which contains 30.8 per cent of the people in the state, there is but one city of any consequence, and not many large towns. Away from the few lines of railway the population is quite sparse: 54.4 per cent of the population live in rural districts. Farming, timbering, stock raising, and the fruit-growing are the chief industries. Relative to its small population, the state is quite rich. In 1910, outside of the city of Portland, only 132,108 census children were reported in the 2265 school districts then existing, or an average of 527 children per district, while the average daily attendance was but 31 per district. As this included all towns and cities except Portland, it will be seen that there are, and must for a long time continue to be, hundreds of small districts scattered over the state. Though transportation of pupils, or the closing of a school and contracting with another to provide education, is permitted, the consolidation of small schools naturally makes but little headway.

The schools follow the state course of study, and are graded and classified. Uniform textbooks are adopted for the state for six-year periods, and districts are forbidden to use any others. The eighth-grade examinations have helped to create uniform state standards of work. The state library law and the state traveling libraries have made real headway in supplying the rural districts with good school libraries. Each county of less than 100,000 people must levy a county library tax of ten cents a school census child, to create a general county school library fund. This is apportioned to the districts on their school census, and must be used to purchase books from lists published by the State Library Board. A fairly good compulsory education law is in force, and provisions made for truant officers. But little has been done so far in agricultural education, though the beginnings of the movement are evident. The school term required now is six months, having recently been increased from three.

Secondary Education — One hundred and eighteen high schools were reported in 1910, seventy-six of which were four-year schools. In 1875 there were but four. Any county may vote to create one or more county high schools; any district may create a high school, if it has sufficient funds to maintain its elementary schools eight months; and any union of districts may be formed to maintain a union high school. For county high schools, a county high school board, consisting of the county judge, two county commissioners, the county treasurer, and the county superintendent, manage the school and estimate and levy the necessary taxes. For union high school districts, boards of control are elected, with the

same powers. Any county may also vote to create a county high school fund by taxation, sufficient to pay the high school tuition of all children in the county. For the first two years all high schools must follow the uniform high school course of study, issued by the State Board of Education, and must use the textbooks adopted by it. Any district may offer, by vote of the annual meeting, instruction in one or more grades above the eighth. Nearly all of the little towns have high schools, there being at least one in every county.

Higher and Special Education.—The State University (*q.v.*) at Eugene and the State Agricultural College at Corvallis stand as the culmination of the school system of the state. Until recently both of these institutions received but meager support from the state, and the state aid is still small. Considering their resources and the small population of the state, both institutions do good work. The state also has a number of small church colleges, nearly all of them old foundations, and only one of them having over \$80,000 of endowment. All of these are open to both sexes. They are:—

COLLEGE	LOCATION	FOUNDED	CONTROL
Willamette University .	Salem	1844	ME
Pacific University . .	Forest Grove	1853	Cong
McMinville College . .	McMinville	1858	Bapt
Albany College	Albany	1867	Presby
Philomath College . .	Philomath	1867	U B
Philly College	Newberg	1891	Friends
Dallas College	Dallas	1900	Un Ev

The state also maintains the Oregon School for Deaf Mutes, the Oregon Institution for the Blind, and the Oregon State Reform School, all at Salem. E. P. C.

OREGON, UNIVERSITY OF.—A coeducational institution established by act of the State Legislature, 1871, and located at Eugene. It is placed under the control of a Board of Regents of thirteen members, ten of whom are appointive by the Governor. The other three members are the State Board of Education: the Governor, the Secretary of State, and the Superintendent of Public Instruction.

The university includes a graduate school; a college of literature, science, and the arts; courses preparatory to journalism, to law, and to medicine; a school of commerce; a college of engineering—including civil, electrical, railway, and chemical; a school of education; a summer school; a school of music; a school of law in Portland; and a school of medicine in Portland.

The requirements for admission to the freshman class comprise the completion of

the usual four-year high school course. One hundred and twenty semester hours of college work, in addition to eight hours of physical training, are required for graduation. The work of the university is very largely elective.

The usual undergraduate degrees of A.B. and B.S. are given for four years of college work, and the graduate degrees of Engineer and of M.A. and M.S. on the completion of a year's additional graduate work.

The University of Oregon, as the State University, is an integral part of the state public school system. With the exception of the schools of medicine and law tuition is free. Support is derived almost wholly from the state. The university campus contains eighty acres of land, lying in the city limits of Eugene. Buildings are ten in number. The value of land and buildings is about \$800,000. The total enrollment of students, January, 1912, was 1554. R. W. P.

ORESME, NICOLE, also known as **OREM, HOREM, and HOREN** (c. 1323-1382)—A French priest whose achievements and scholarship entitle him to rank as one of the great educators of his time. He entered the Collège de Navarre at Paris in 1348 as a student, and in due time became a professor there, and was later placed at the head of the institution. In 1377 he became Bishop of Lisieux, and held this position until his death. He translated various works on Aristotelian philosophy from the Latin into French, and was well known for his lectures on philosophy and mathematics. His *Tractatus de latitudinibus fornarum* was very influential, and after printing was invented it appeared in several editions. He also wrote a *Tractatus proportionum*, which was printed at Venice in 1505. His most important work from the standpoint of mathematics, however, was the *Algorismus proportionum*, in which it clearly appears that he was the inventor of the fractional exponent now so commonly used in algebra. D. E. S.

ORGANIC MEMORY.—Whenever any organic tissue functions, it tends to change its structure as a result of its activity. The nervous system exhibits in a higher degree than any other of the organic tissues this susceptibility to experience. Whenever a portion of the nervous tissue has been used in the performance of any act, the structure of that part of the nervous tissue is so modified that it is easier for the act to be repeated at a later time. The ability of tissues to retain the results of past experiences is designated "organic memory." C. H. J.

ORGANIC SENSATION — All of the internal bodily organs, especially those in the abdomen, are supplied with sensory fibers. Any change in the condition of these organs, especially if it is pathological in character, arouses sensory processes. The sensations which result from such stimulations are especially important in determining the emotional background of experience. The ancients recognized this fact in their reference of emotions to the internal organs. In popular parlance we refer to the heart and other organs as seats of the emotions. How far the relations of the emotions to these organs are due to incoming currents of sensory stimulation, and how far they are due to the motor processes in these organs, may be a matter of discussion, but it is clear that the sensory experiences that arise from the internal organs contribute the general background of all conscious experience. Various classifications have been proposed for these organic sensations. Such classifications usually distinguish between the sensations arising from the different internal organs. It is to be noted, however, that the qualitative differences are not so important in this case as in the case of sensations coming from the external world. There is a very large element of pleasure or pain in the organic sensations. This fact appears in all of the discussions of the relations between these sensations and the emotions. C. H. J.

ORGANIZATION OF CLASS WORK. — See SCHOOL MANAGEMENT.

ORGANIZATION, SCHOOL. — Every school system mediates between social needs and conditions and the physical and mental nature of childhood. The school as an institution serves the world and the individual; its adjustments are, therefore, at once sociological and psychological. Wherever the activity of the school system is primarily an arrangement determined by social ideals, public finance, and other distinctly social factors, we have an administrative method; wherever they primarily take into account the nature of the pupil and his growth, we have an educative or teaching method. Such methods are the means of executing the purposes of an institutional education. They are in large degree flexible, but underlying them is a more or less definite and somewhat fixed structural organization. Thus, behind administrative methods are the organized units of the school system, — kindergarten, elementary schools, high schools, colleges, universities; and behind the teaching process is a more or less

definitely established course of study which is the basis of all teaching. Even the social order of a school and the discipline of its members rests upon a definite organization of rules, well-accepted customs, and habits of orderly procedure. It may be said, then, that the methods of a school may be differentiated into (1) its relatively fixed and static elements, and (2) its relatively flexible and dynamic elements. The former are included under the term "school organization"; the latter under "school methods," i.e. methods of administration, management, teaching, discipline, etc. H. S.

ORIENTAL STUDIES. — In Antiquity. — The earliest actual impulse to the study of Oriental languages on the part of the West appears to have arisen in the natural desire for intercommunication on matters of mutual concern. From the remotest times trade and commerce had a paramount part in bringing this about, although it must also be emphasized that the factors of war and diplomacy played hardly less conspicuous rôles. As is well known, there had been business and political relations between Greece and the Orient long before the clash of arms between Hellas and Persia in the days of Darius and Xerxes; and the countermarch into the East by Alexander the Great a century and a half later was not without its commercial aspect.

International relations between Europe and Asia may be regarded as the source from which sprang the study of Oriental languages in the West. In some respects Themistocles, the political refugee from Athens to the Persian court of Artaxerxes I (460 B.C.), who in a year acquired sufficient fluency in Persian to be able to converse freely with the Oriental monarch without the medium of an interpreter, may be accounted a forerunner (Plutarch, *Them.*, 29); but the general attitude of the Greeks in considering everything that was not Hellenic to be "barbarian" was not favorable to the study of Eastern tongues.

On the other hand, the Orientals were far more liberal in their readiness to acquire a knowledge of foreign languages, and this position seems to have been maintained to the present day. The same freedom from a narrow linguistic point of view may have contributed materially to the readiness of Orientals to act as interpreters where other tongues are concerned. In Egypt royal encouragement was given to this attitude by Psammetichus, who recognized the practical ends in view and sent Egyptian children to a colony of Greeks and Carians in the Nile delta to learn Greek; and in this manner, according to Herodotus, arose the caste of

Egyptian interpreters whose services were employed by the Father of History himself, in his ignorance of the local tongue (*Hdt.*, 2. 154, 125). At a still earlier time the Median king Cyaxares is said to have sent children to live among his Scythian immigrants that they might learn the Scythian language (*ibid.*, 1. 73). A similar class of professional interpreters must have existed in Asia Minor, for Greek traders negotiated with Scythians on the Pontus Euxinus "through seven interpreters and seven tongues" (*ibid.*, 4. 24; cf. Arrian, *Anab.*, 4. 3. 7). When the Persian royal claimant, Cyrus the Younger, communicated with the Greek mercenaries in his army, it was through an interpreter as intermediary (Xenophon, *Anab.*, 1. 2. 17); and the same was true of Xenophon in conferring with the Pontic Mossynæci (*ibid.*, 5. 4. 4). In India the Greek historian Onesicritus the Cynic, who accompanied Alexander the Great to the East, sought to interchange ideas with the Brahmins, though this was possible for him only through the aid of three interpreters; and as to the futility of endeavoring to expound Indian philosophy in such a manner, one of the Hindu sages justly remarked that to attempt it was to "expect water to flow pure through mud" (Strabo, p. 716).

Significant in this respect, as showing in later times the Oriental facility for the acquisition of foreign tongues, is the widespread use of the common word for "interpreter" derived from the Arabic *tarjumān*, "translator," which has given rise to a whole family of words like Italian *dragomanno*, *turcimanno*, French *dragoman*, *trucheman*, English *dragoman*, Old Church Slavic *tlǫmāši*, Middle High German *tolmetsche*, New High German *Dolmetsch*, Lithuanian *tūlka*, and Dutch *tolk*, all signifying "interpreter."

With the growth of ancient civilization it was impossible for the West to rest content with a knowledge of Oriental languages merely for practical purposes, for some of these tongues possessed literatures of more or less merit, and the Greek mind craved to know what might be the contents of these "barbarian" books. We need give no special credence to an isolated Iranian tradition that one of the two original copies of the Avesta was translated into Greek at the command of Alexander the Great "as information which was connected with the ancients" (*Dinkart*, 3. 5, tr. West, *Sacred Books of the East*, 37. p. xxxi.; cf. *ibid.*, 47. 82), although the Macedonian invader and the scholars who accompanied him may actually have interested themselves in knowing something about the famous Zoroastrian scriptures. We may pass a similar judgment on the allegation that the Alexandrine Peripatetic philosopher Hermippus translated 2,000,000 "verses composed by Zoroaster" (Pliny, *Hist. Nat.*, 30. 2. 1); indeed, it is not impossible that these two

stories are in some way connected. At the same time, however, we must emphasize the fact that there were authentic cases of translation from Oriental languages into Greek and Latin. To the Greek group belong the translations of Berosus from the Babylonian by Philo Byblius, and Menander of Tyre from the Phœnician, and by Manetho from the Egyptian. All these works, which were historical in theme, have unfortunately vanished, except for scanty fragments; but it has recently been shown by Bezold and Boll ("Reflexe astrologischer Keilinschriften bei griechischen Schriftstellern," in *Sitzungsberichte der Heidelberger Akademie der Wissenschaften*, 1911, no. 7) that there was direct translation of extant Greek omen-literature from the Babylonian. In the Byzantine period there was considerable translating from Oriental languages (cf. Krumbacher, *Geschichte der byzantinischen Litteratur*, 2d ed., Munich, 1897), and we still possess a Greek version of the *Periplus* of the Carthaginian Hanno, which has recently been rendered into English by Schoff (Philadelphia, 1912).

The more practical Romans had the work of the Carthaginian Mago on agriculture translated into Latin at the command of the Senate; and Sallust mentions among his sources on African history some versions made for him from "the Punic books said to be those of King Hiempsal" (*De Bello Jugurth.*, 17).

When the Oriental religions began to permeate the West, the new need arose of a more precise understanding of their liturgies and sacred writings; and this necessity became still more urgent in the case of the demands made by Christianity, when the Western Church grew suspicious of the Septuagint rendering of the Bible (that earliest Greek version of an Oriental sacred book), and sought for a Latin version of the Scriptures which should be based on the original tongues. This demand was recognized as early as the third century A.D., when Origen prepared his *Hexapla*, with a presentation, as far as was then possible, of the Hebrew by the side of the other texts concerned. In the latter part of the fourth and the early part of the fifth century St. Jerome undertook the task of preparing the Latin Vulgate; and, to perform the work, he devoted himself for several years to the study of Hebrew, particularly among the Jews of Bethlehem.

Nevertheless, there is no trace, throughout this entire period, of the study of Oriental languages for other than purely utilitarian or religious ends. Though many of the authors who wrote in Greek were Orientals,—for example, Ptolemy and Plotinus were Egyptians, Porphyrus and Iamblichus Syrians, Dioscorides a Cilician, Galen a Mysian, Dio Chrysostom and Dio Cassius Bithynians, Lucian a Comagenian, and Strabo a Pontine; while for the Latin writers we may mention the Africans

Apuleius and St. Augustine, — these scholars have given us no glimpse of their native languages. Indeed, almost the only specimens of Oriental tongues extant in classical texts are the few lines of Punic in the *Pœnulus* of Plautus (ll. 930–949) and the line of Old Persian in the *Acharnians* (l. 100) of Aristophanes, for the unintelligible jumbles on Greek magic papyri are too uncertain to be considered here. There was, however, more or less knowledge of at least scattered words, as when Plato (*Cratylus*, 410 A) alludes to the resemblance between the Greek and the Phrygian designations for “fire,” “water,” “dog,” etc.; and all this led to the compilation of glossaries, in which cognizance is taken of Oriental words, as in the one ascribed to Hesychius.

But at this very time a new force was gradually coming into being, destined to set at naught the exclusiveness of the Græco-Roman world with regard to the Orient. This force was Christianity, which sought to make the Scriptures accessible to all nations in their own languages; and for that reason missionaries were obliged to be able to expound the Bible and to preach in the vernaculars of those to whom they were sent. By the fifth century the Syrian bishop Theodoret could justly say, in his *De curandis Græcorum affectibus* (ed. Migne, *Patrologia Græca*, Vol. LXXXIII, p. 948), that the Bible had then been translated into Egyptian, Persian, Indian (i.e. South Arabic), Scythian, and Sauromatian, and many more, these including Armenian and, before long, Georgian. Apart from the Bible and except for theological literature, however, there was little effective activity in Oriental studies, although mention may be made of a brief glossary of ninety words in Armenian and Latin, belonging to the tenth century (ed. Carrière, Paris, 1886), as well as of the *Codex Cumanicus*, dating from the early fourteenth century (ed. Kuun, Budapest, 1880), which contains, besides a Latin-Persian-Cumanic glossary, a number of texts in the latter language.

After centuries of practical oblivion the study of Oriental languages showed signs of revival when, in 1259, Raymundus de Pennafort urged the Dominican order to acquire Hebrew, while at the Council of Vienne (1311–1312) Clement V ordered the establishment of professorships of that language at all universities. For obvious reasons Hebrew long held the first place in Oriental studies, though Arabic, a knowledge of which was requisite for disputation with the Moors of Spain, also received attention. It was, however, Protestantism, with its insistence on the Bible only, that gave the great impetus to the study of Oriental tongues, though Protestantism had already been anticipated in a measure by the rationalism of the Renaissance, with its desire to delve deeply into all things secular. The

first non-Oriental Hebrew grammar was prepared in 1506 by the distinguished Humanist Reuchlin (q.v.), who has justly been called the father of Jewish studies among the Christians; the earliest Arabic grammar was published by Pedro de Alcalá in 1505 and ranks as one of the landmarks of Semitic philology. The first grammar of the cognate Ethiopic was issued by Marius Victorinus in 1548, and of Syriac by Johannes Albertus Wicdemannstadius in 1558; while in 1539 Theseus Ambrosius essayed comparative study in his *Introductio in Chaldaicam linguam, Syriam atque Armenicam et decem alias*.

During this period the progress of Semitic studies (see JEWISH EDUCATION) was especially noteworthy, yet even Sanskrit received some attention in the sixteenth century from the Italian Philippo Sassetti, who lived in India from 1583 to 1588, and whose *Letters* (ed. Marucci, Florence, 1855) contain the earliest European information regarding this ancient language of India. It was, moreover, about the middle of this same century that the Jesuits established printing presses at Goa, and “Sanskrit, Tamil, Malayalam, and Syriac were studied by the Portuguese Jesuits residing there [at Ambalacatta] with great success” (see Burnell, “Early Printing in India,” in *Indian Antiquary*, Vol II, p. 90), while the first Tamil printed text, a Tamil translation of a Portuguese *Doctrina Christam*, appeared at Cochín in 1579. The transition from the more specific study of Semitic to that of Indo-Germanic had already been made by a Norman scholar named Guilicinus Postellus, who in 1538 devoted attention to Hebrew, Syriac, Samaritan, Arabic, Ethiopic, Georgian, and Armenian, besides a number of European languages, although he, of course, shared the prevailing theory that Hebrew was the parent of all languages. In yet another Oriental-Occidental field the famous Joseph Justus Scaliger published, in 1597, our earliest list of Gypsy words, as well as a brief specimen of the later Persian tongue.

The seventeenth century still further widened the knowledge of Oriental languages, and grammars or lexicons (or both) were prepared in a succession that is historically worth recording: Malay (1603), Turkish (1612), Tagalog (1613), Persian (1614), Canarese (1616), Armenian (1624), Georgian (1629), Coptic (1643), Congocese and Konkani (1659), Chinese (1667), and Amharic (1698), while in 1664 the Lutheran missionary, Heinrich Roth, learned Sanskrit in order to be able to dispute with the Brahmans, and late in the same century the famous Leibnitz made a determined attack on the old view that Hebrew was the ancestor of all languages.

In the eighteenth century, during which the first serious study of Oriental dialects was begun by Johann Joachim Schröder in his *Thesaurus linguae Armeniæ antiquæ et hodiernæ*

nae, published in 1711, and when Oriental epigraphy was inaugurated in 1754 by Barthélemy in his investigation of the Palmyrene inscriptions, attention was devoted to the southern Indian dialects of Singhalese (1708) and Malayalam (1713), as well as to Tibetan (1722), Telugu (1728), the *lingua franca* of Hindustani (1741), Bengali (1743), Fanti and Akkra (1764), Chuvash (1769), Chermish and Votyak (1775), Mahratta (1778), and Kurdish (1787).

The close of the eighteenth century was destined to see a discovery, to which reference has already been made, that was to revolutionize the entire outlook of Oriental studies, and that was fated, in the following century, when combined with the decipherment of the Old Persian inscriptions, to establish on a scientific basis the vast domain of Indo-European philology, as well as to give inspiration for the comparative study of Dravidian, African, and Polynesian languages. This was the opening to scholars of the West of a general knowledge of Sanskrit. Since that time the progress of Oriental studies has been fully assured as a branch of Occidental learning when conjoined with the other departments of Western and Eastern research to which allusion has been made above.

During the past generation or two the study of Oriental languages as one of the regular forms of educational training has received a recognized place in almost all the advanced institutions of learning in the Occident; and the Eastern tongues have been given a position in the curriculum side by side with the classic languages of antiquity and the modern vernaculars of Europe. From a pedagogical standpoint the value of Eastern studies is fully acknowledged, and their worth is more and more generally granted from the practical as well as from the cultural point of view. The reason for this is twofold. In the first place, the West is deeply indebted to the East for the contributions which the latter has made to our knowledge of antiquity. In the second place, Orient and Occident are more closely united to-day than ever before in history, and a mutual understanding of each other's storied past and of each other's present conditions — best gained through such special linguistic knowledge — is a potent factor in furthering the world's aims of civilization. Striking prominence has recently been given to the weight of this consideration through the rapid strides which Asia has lately made in the line of progress.

Oriental Studies in General. — As a science the study of Oriental languages is a relatively young development in the West, even though from the earliest times due recognition has been accorded to the practical knowledge of Eastern vernaculars. It was natural that the more special impetus to the movement should come first from a desire to study the

Scriptures in the original languages as a requisite basis for true understanding of the Bible. Although the beginnings had been made in the days of the Church Fathers, it was only after the end of the Middle Ages that Christian scholars commenced to avail themselves more and more of the linguistic attainments of Jewish rabbis, and to gain through their instruction a more technical knowledge of the text of the Old Testament. (See JEWISH EDUCATION.) The establishment of a trilingual college for Latin, Greek, and Hebrew in 1516 at Louvain, Belgium, was but one of several kindred foundations on the continent of Europe and in Great Britain that were destined later to become great centers of Oriental learning. Hebrew, followed by Arabic, thus led the way to a broader study of the cognate Semitic languages, — a field that has been developed with special success during the last half century. In the line of Indo-Germanic philology, on the other hand, the introduction of a knowledge of Sanskrit, in the eighteenth century, was the most active agency in broadening the path that had long been trodden by Greek and Latin scholars; and the thoroughly scientific methods employed in Sanskrit philology were early accepted as models to be followed in other branches of Oriental research, especially in the entire domain of Indo-Germanic linguistics.

University instruction was not the only factor that played a part in promoting Oriental studies, for the mercantile and political relations which had been gradually developing between Europe, Asia, and Africa, especially after India was incorporated in the British Empire, were a prominent feature in this respect. Governments recognized the value of giving financial aid to special seminaries which had for their object the training of young men for commercial and diplomatic service in the Orient. One of the earliest of these institutions was the *Kaiserliche-Königliche Konsular-Akademie*, founded at Vienna in 1754 by the Austrian government, and of like purpose was the establishment of the *École spéciale des langues orientales vivantes* at Paris in 1795, while mention should also be made of the still older *Reale Istituto orientale* founded at Naples in 1727. Later developments along corresponding lines are the *Lehranstalt für orientalische Sprachen*, organized at Vienna in 1851; the creation of an extensive corps of special instructors for Oriental languages in connection with the work of the University of St. Petersburg since 1854; the ministerial subsidies devoted to the *Seminar für orientalische Sprachen* at Berlin since 1887; and the establishment of the *Orientalische Handelsakademie* at Budapest in 1891. In England the University of London likewise includes a special School of Modern Oriental Languages; and Oxford and Cambridge each have chairs or lectureships for a score and

more of Oriental specialists, with kindred representatives in all the other universities of Great Britain. Throughout the continent of Europe every university is equipped proportionately, or even in much larger degree. Nor has North America been far behind since the time when the real foundation for Asiatic studies in the New World was laid, more than half a century ago, by the noted Sanskritist, William Dwight Whitney, of Yale, who died in 1894. In South America, on the other hand, the serious study of Oriental languages is still to be inaugurated.

Hand in hand with the several movements already described there has gone also the strong impulse imparted by the work of the learned societies whose special aim is devotion to various lines of Oriental research. One of the earliest of these bodies was the Asiatic Society established at Calcutta in 1784; while to-day there is a flourishing Oriental society in nearly every country of Europe, and North America can likewise claim its own Oriental Society, founded in 1842. Among the most important of the European societies are the English Royal Asiatic Society of Great Britain and Ireland (founded in 1834), with its daughter societies — the Bombay, Ceylon, China, Korea, and Straits Branches; the German *Deutsche morgenländische Gesellschaft* (1845), *Deutsche Orient-Gesellschaft* (1898), *Vorderasiatische Gesellschaft* (1895), and *Münchener orientalische Gesellschaft* (1901); the Dutch *Koninklijk Instituut voor de Taal-, Land- en Volkenkunde van Nederlandsch Indie* (1851); the French *Société asiatique* (1822); and the Italian *Società asiatica italiana* (1887). These societies all publish their own journals, and among other periodicals relating to Oriental languages may be noted the English *Journal of the African Society*; the East Indian *Indian Antiquary*; the American *Journal of Semitic Languages and Literatures*; the Belgian *Muséon*; the German *Zeitschrift für Assyriologie*, *Zeitschrift für ägyptische Sprach- und Altertumskunde*, *Zeitschrift für afrikanische, ozeanische und ostasiatische Sprachen*, *Archiv für das Studium deutscher Kolonialsprachen*; the Austrian *Wiener Zeitschrift für die Kunde des Morgenlandes*; the Swedish *Sphinx*; the French *Revue sémitique*, *Recueil de travaux relatifs à la philologie et à l'archéologie égyptienne et assyrienne*, *Revue d'assyriologie*, and *T'oung Pao*; and the Italian *Studi italiani di filologia indo-iranica, Oriens Christianus*, and *Bessarione*.

As this survey implies, the breadth and scope of the studies pursued have grown in a remarkable manner during the last fifty years. The day is past when either Sanskrit or Hebrew and Arabic, or any other single one of the two great linguistic families to which they belong, can claim the priority of attention which they once enjoyed. A place is now found beside them for the study of the Chinese classics, for

questions relating to Japanese, for Central Asian dialects, Philippine tongues, African vernaculars, and Polynesian speech forms. The East itself, which had long been obliged to cultivate European tongues for practical reasons, is now devoting serious attention to its own individual languages as a subject worthy of profound consideration. The Asiatic Society of Japan was founded at Tokio in 1872, and the Siam Society at Bangkok in 1904; though to foreign initiative are due the establishment of the *École française d'extrême orient* at Hanoi in 1898 and of the *Vostochny institut* ("Oriental Institute") at Vladivostok in 1899.

The Practical Value of Oriental Studies. —

The practical value of a training in Oriental languages will be self-evident for the claims made upon the missionary, diplomat, military officer, or merchant who is to live among the peoples speaking those tongues. Even though in many places English or French may serve as a medium of communication sufficiently well to answer ordinary requirements, nevertheless when once the Westerner leaves the beaten track, he will be practically helpless without a knowledge of the vernaculars or of the *lingua franca*, which may be Arabic, Persian, or some other Oriental language. While for the merchant or the military officer in the East it may be enough to learn merely the modern spoken languages or dialects, precisely as the ordinary man in rank and file or at the desk acquires a speaking knowledge of French, German, or Spanish, it is incumbent on the missionary and the diplomat in the Orient to know also the ancient Eastern languages and their literatures. The religious and secular life of a people can be studied accurately only in the light of a thorough knowledge of their past history and literature; and this fact equally presupposes a knowledge of their language from its earliest accessible period. No translation, however skillful, can suffice, and for the Oriental field in particular the task of the translator is beset with innumerable perils. If the trained investigator often stands perplexed before some apparently absurd, cruel, or obscene custom of the particular people with whom he is brought in contact, how much more helpless must he be who has had no real scientific training, yet who recognizes that effectively to remove the evil he must first recognize and eradicate its cause. To this lack of training on the part of those who have sought to spread the Gospel, many of the criticisms of the older school of missionaries are due; on the other hand, those missionaries who have best understood their people have almost invariably been the ones who have had the greatest success both in winning converts and in every other respect. To the theologian Oriental studies make a special appeal, for the light that is cast upon the language and the religion of the Old Testament from

the Semitic tongues, religions, literatures, and customs is incalculable. To the teacher of languages or of literatures some Oriental study is essential if he is to do his best work. Sanskrit holds in this respect the first place as the oldest member of the Indo-Germanic group of languages; and its grammar explains phenomena in other tongues that are otherwise inexplicable. In fact, it is even more essential in this respect than even Greek and Latin. If the specialist in Church history and in the history of dogma must be familiar with Oriental languages, it is none the less true that the historian of philosophy must be equally familiar with the thought of the East; and in like manner the historian not only of such sciences as mathematics, chemistry, and medicine, but also of certain periods and countries of Europe must seek Oriental sources, as for the history of the Crusades or of Spain, Greece, and Malta. Finally, no survey of literature is complete without some knowledge of the literary types found in Sanskrit and Pali, Syriac and Arabic, Chinese and Japanese, Persian and Egyptian.

Oriental Studies and their Educational Pursuit. — The difficulties of Oriental study are exaggerated in the popular mind. This is probably due in great part to the fact that they are written in unfamiliar scripts. Yet inherently these tongues are not really hard to master, and the grammar of the Semitic and of most of the Indo-Germanic Oriental languages is comparatively easy. The only real difficulty is in the vocabulary. The teaching of Oriental languages will probably never begin before Junior year in college, although there is no real ground for making this limitation beyond the fact of the insistent demand of studies that are seemingly more urgent and the fact that Orientalism will attract only a chosen few. Grammars, lexicons, and chrestomathies exist in abundance for all the better known tongues, and only in the verb categories of Semitic will the average beginner find anything that is really unfamiliar to him. A knowledge of classics is usually possessed by those who take up Oriental studies. Although such knowledge is not an indispensable prerequisite, and although it may even occasionally be questioned whether some of the students who undertake the study may not approach it more independently without a technical familiarity with Greek and Latin; yet teachers, on the whole, have thus far in the West found their best adapted scholars among those who have previously been equipped with the essentials of one or both of the classic tongues. To the student who perseveres there is a vast field where he can scarcely fail to reap some fruit, particularly as in almost every Oriental language there are large bodies of literature as yet only inadequately known, or even entirely uninvestigated, in many cases not even edited.

The one real difficulty is that there is, under present conditions, a lack of teaching positions for Oriental languages, except perhaps in the Semitic field; and the hope is to be cherished that larger opportunities may be opened, as are due, to scholars who devote themselves to this branch of research. On the other hand, it can scarcely fail to make for mental poise and the avoidance of the peril of overspecialization if one has some Oriental subject for his diversion, if not for his domain of special study and investigation.

There is, however, a word of warning to be sounded in regard to what may be called pseudo-Orientalism. The tendency to seek for novelty and for superficial analogy has been prejudicial to the cause of true Eastern studies, especially in view of the close connection of much of Oriental literature with religion. Astro-mythological theorists, for example, and the "pan-Babylonians" have brought some branches of Semitic studies into critical discredit; while pseudo-Buddhists and other imperfectly informed followers of Oriental systems of thought have at times detracted from appreciation of the true value of Sanskrit and Pali studies. Lack of genuine knowledge has prevailed somewhat widely, it must be confessed by the competent critic, and has led too many of the weaker minds astray. There is, then, all the more reason for the sober and scientific study of Oriental languages and for the teaching of these disciplines in a manner that shall adequately set forth their true dignity and their true worth.

ORIENTATION OF THE SCHOOLHOUSE. — See ARCHITECTURE, SCHOOL.

ORIGEN (185-254). — The greatest of all the early Christian teachers was an Egyptian, the son of Leonides, a teacher of rhetoric, who gave him a liberal education in all the arts and sciences then known. He was a precocious scholar, a pupil of Clement of Alexandria (q.v.)

and of Ammonius Saccas, the founder of the Neo-Platonic Philosophy. He became thoroughly familiar with the teachings of Plato and all the Greek philosophers and with the Hebrew Scriptures. At the early age of eighteen he was placed at the head of the great Alexandrian School (see CATECHETICAL SCHOOLS). Here his activity as a teacher and writer was incessant, and by his untiring industry and irresistible logic he soon won the title of *Adamantius*. His fame spread far and wide, and he was consulted by scholars, statesmen, and leaders of the Church, with whom his opinions carried great weight. Under his direction the Alexandrian School became the greatest center of learning in the world.

In the persecution under Maximia, Origen was driven from Alexandria and found refuge in Cæsarea, where he established a new Catechetical School (*q.v.*), which soon surpassed that of Alexandria. Here he passed the rest of his life in prodigious labors. The opinion of the learned men of Palestine was voiced by Gregory of Nyssa (*q.v.*), who described him as "the Prince of Christian learning in the third century." Fortunately we have a contemporary record of his educational methods by Gregory Thaumaturgus (*q.v.*), who was his pupil for five years at Cæsarea. His *Panegyric upon Origen* is one of the classics of education and gives us a vivid picture of this great educator and his work. The system as described by him was remarkable for its breadth, thoroughness, and high moral tone. The first stage consisted of a careful training in grammar and logic, designed to teach the student the exact meaning and use of words and to enable him to investigate truth and detect false arguments. He was then introduced to the study of the physical world through the sciences of physics, astronomy, and geometry. Next came the study of ethics, based upon the four Platonic virtues and including an examination of all known ethical systems, in order to incorporate everything of permanent value found in them. The object, however, was not so much to formulate a theory of ethics as to build up character. Gregory's words are significant: "Much as we learned from the words of Origen, we learned still more from his example." Evidently there was a peculiar charm about this great teacher which endeared him to his students, while his pure and noble character impressed them not less than his intellectual powers. His whole educational system culminated in the study of Holy Scripture, to the exposition of which he devoted his highest powers. His literary labors were enormous. St. Jerome (*q.v.*) says he wrote 2000 books. In his *Hexapla* he brought together in one polyglot collection the best versions then extant of the Old Testament. His *First Principles* was the first attempt ever made to create, with the

help of philosophy, a science of Christian Doctrine and was one of the most influential books ever written, although disfigured by some extravagant speculations. His *Commentaries* and *Homilies* upon Holy Scripture, of which only a few remain, were voluminous and valuable. His apologetic work, *Contra Celsum*, his *Stromata*, in which he compares the doctrines of Christianity with the teachings of philosophy, and his *Letters* complete the list. W. R.

ORIGINAL AND ACQUIRED CHARACTERISTICS. — See **ACQUIRED CHARACTERISTICS**; **NATIVISM**.

OROSIUS, PAULUS (fl. 415). — Historian and theologian, a native of Spain. Of his little is known before the barbarian invasions of Spain, about 409. Soon after this he came into personal relations with St. Augustine (*q.v.*), whom he represented rather unsuccessfully when Augustine sought to procure the condemnation of Pelagianism in Palestine. In 417–418 Orosius was back in Hippo with St. Augustine. At this time he wrote his famous history, *Historiarum adversus paganos libri septem*. It was undertaken in proof of a position assumed by Augustine in his *City of God*, rather than with a purely historical purpose. Orosius aims to prove by an outline of general history that before the advent of Christianity the world suffered even more from plagues, pestilences, famines, wars, and other disasters than since that event. In this historical sketch, Orosius meets successfully the pagan charge that the introduction of Christianity and the cessation of heathen worship were the causes of the recent disasters to the Roman world. Orosius made use of the Old and New Testament, Josephus, Eusebius, and also Livy, Tacitus, Suetonius, Cæsar, Cicero, and other pagan historians. In turn the work was used by Bede and medieval writers generally. As an independent authority, Orosius is of importance only in the latter part of his work, from about A.D. 378 to the end A.D. 417. The book was translated rather freely into Anglo-Saxon by Alfred the Great, and its popularity in the Middle Ages was very great, serving as the accepted manual or textbook of general history. The other works of

Orosius are theological in character and connected with the controversies of his time.

ORPHANS, EDUCATION OF. — The term applied to the institutions now generally termed orphan asylums, orphanages, or orphan houses or schools, was hospitals; and under the caption **HOSPITAL SCHOOLS** the historic development of these institutions and of this type of education has been traced. Following the Reformation such institutions, more or less independent of the Church and replacing the old ecclesiastical foundations which had the care of orphans as one of their functions, became quite numerous. Especially with the seventeenth century was there a marked development which, to the present day, has given a distinctive place to this type of educational institution. A brief historical sketch outlining the details given under **HOSPITAL SCHOOLS** will furnish a perspective for judging present conditions; see also **PICTISM**; **FRANCKE**; etc.

Historical. — The earliest expression of charity in human society of which we have any record was exercised in behalf of orphan children. The Hebrew Scriptures in most emphatic terms repeatedly enjoined responsibility for the care of the widow and the orphan: "Ye shall not afflict any widow or fatherless child. If thou afflict them in any wise and they shall cry at all unto me, I will surely hear their cry, and my wrath shall wax hot and I will kill you with the sword; and your wives shall be widows and your children fatherless" (Exod. xxii, 22-24). "And the Levite (because he hath no part nor inheritance with thee) and the stranger, and the fatherless, and the widow, which are within thy gates, shall come, and shall eat and be satisfied; that the Lord thy God may bless thee in all the work of thine hand which thou doest." (Deut. xiv, 29.)

Nearly two thousand years later a New Testament writer defined religion in terms of charitable service rendered the widow and the fatherless: "Pure religion and undefiled before God and the Father is this, to visit the fatherless and widows in their affliction and to keep himself unspotted from the world." In the Apostolic constitutions of the primitive churches bishops were commanded "to take care of the orphans; see that they want nothing." (See Chastel's *Charity of the Primitive Churches*.) Throughout the Middle Ages endeavor in behalf of orphan and dependent

children was under the direction of the Church. The Emperor Constantine after his conversion from Paganism to Christianity declared himself the patron of orphans and other defenseless children.

The modern orphan asylum as a charitable institution maintained apart from church or monastery arose in the latter part of the seventeenth century. The best known of those early asylums was the one established in 1695 in Halle, Germany, by August Hermann Francke (*qv*). It was opened on the goodly capital of three and one half dollars. On finding this sum at one time in the contribution box which he had fastened up in his house, Francke exclaimed, "With this must I do a great work." With such small beginnings he began to gather in, to feed, and to instruct orphans and street beggars. Later he began to build, adding structure upon structure as the numbers increased. His establishment still remains — a quarter of a mile in length and six stories high, built around a long courtyard. Francke's orphanage and home for dependent children became the model and inspiration of many others established during the following century in Germany and other countries, including the United States. In his *Annual Report* as Secretary of the Board of Education of Massachusetts, Horace Mann (*qv*) in writing of his visit to the German States says, "Another fact which will strike the visitor to these countries (German States) with mingled sorrow and joy, is the number and populousness of their orphan establishments. In the great cities almost without exception, one or more of these is to be found." The orphan houses originally established for the care of soldiers' orphans were afterwards appropriated to orphans of other classes. Institutions established in the United States after the Civil War for soldiers' orphans have in recent years followed a similar course, in some states becoming state industrial schools for dependent and delinquent children.

In some of the orphanages of European countries the training given the children of soldiers and sailors was intended to fit the boys for the occupation of their fathers. Thus in the same *Report* quoted above the writer says: "In the Royal Orphanage House at Potsdam there were a thousand boys all children of soldiers. Great attention was given to physical training. As the boys were destined for the army it was thought important to give them agility and vigor. The boys practiced gymnasium exercises, such as climbing poles, ascending ropes, flinging their bodies round and round over a bar while they hold on only by the bend of the legs at the knee joints, vaulting upon the wooden horse, etc., until their physical feats reached a point of perfection which I have never seen surpassed except by professional circus riders and rope

dancers." At Brest was a similar institution for sailors' orphans which gave a special nautical and military education, including management of sails, fife, drum, rowing, swimming, whistling, gun practice, boxing, etc. (Barnard *American Journal of Education*, Vol. XXI, 378-80.) This program of training is still in vogue in similar institutions, as illustrated recently by the coronation drill exercises in honor of George V rendered by the boys of the Reedham Soldiers' Orphan Asylum, Purley, which is directly under His Majesty's patronage.

In the early period of this country orphan and dependent children were cared for in public almshouses, where they were usually housed with the adult paupers. (See POOR LAW AND EDUCATION.) Their removal from these institutions beginning about the middle of the last century has been a long and tedious process and is not yet entirely accomplished. (Folks, *The Care of Destitute, Neglected, and Delinquent Children*.)

Parallel with this movement, but more rapid in progress, has been the founding of orphan asylums.

Prior to 1801 only six orphan asylums had been founded in the United States. By 1831 fifteen more had been established. After 1831, their number increased rapidly. During the twenty years following 1831 fifty-six orphanages and homes for destitute children were founded. "It is not possible to trace the establishment of children's institutions after 1850 in detail. It may be stated that everywhere they increased in numbers and in diversity of character and objects. Not including some Central and Western states from which returns have not been received, forty-seven new constitutions were organized in the fifties, seventy-nine in the sixties (notwithstanding the civil war) and twenty-one in the first half of the seventies." (Folks, *l.c.*)

Present Conditions.—The latest report of the U. S. Bureau of the Census of Institutions gives forty-four hundred as the total number of benevolent institutions in the United States. Of this number eleven hundred are orphanages and children's homes. These are broadly classified as public, private, and ecclesiastical. In round numbers there are five hundred private, an equal number of ecclesiastical, and one hundred public. The total number of children in these institutions is about one hundred thousand and the average expense of maintenance ten millions of dollars. New York ranks first among all of the states in both the number and proportion to population of children's homes having one hundred and fifty of these institutions. Of this number only five are public homes, while the remainder are divided about equally between private and ecclesiastical foundations. Twenty-six states have no public institutions for children. Whether a state has many or few orphanages does not depend upon the population or the number of

dependent children, but rather on the policy pursued in caring for them. If an institutional policy has prevailed, there will be many institutions; if a placing-out method of care,—that is, the placing of the dependent child in private homes at board, at service, or by adoption,—there will be few institutions. Thus, Iowa with a population of two and a quarter millions reports but twelve institutions, while New Jersey with a population of half a million less reports forty-six homes.

The number of orphanages and children's homes has increased rapidly for the past twenty-five years. From 1890 to 1903 the total number of new homes opened was about four hundred. Many of them, especially those established upon ecclesiastical foundations, have had their origin in religious or sentimental impulse rather than from a clear recognition of the need of such a charity. The result of this blind philanthropic endeavor has in some instances been an over-planting of institutions on the one hand and indiscriminate charitable relief on the other, as shown in the admission of many children whose separation from their homes was merely an economic convenience rather than a necessity.

Systems of Organization.—There are two types of orphan homes—the congregate or barracks type and what is known as the cottage system. In the congregate homes the children live in one large building, which contains kitchen, dining room, dormitories, playroom and schoolrooms. In the cottage system the children of the institution are divided into small groups of from fifteen to twenty-five, each group having its own cottage home. There are several modifications of this form of housing from the completely separate and individual cottage home and school to that in which the school, kitchen and dining room are in central buildings, the separate cottages providing dormitories and perhaps sitting rooms for the various groups. Since the advantage of the cottage plan over the congregate lies in its nearer approach to the private family home, it follows that central features for a group of cottages like the kitchen or dining room, where all of the children assemble three times a day, are opposed to the chief aim sought in adopting the family-group idea. In a well-managed cottage system the kitchen and dining room in each cottage become practical training schools in which the children learn to manage a range, to cook, prepare and serve meals, with all of the innumerable accessory duties and responsibilities pertaining thereto. The cottage sitting room and library contribute in a similar way to the home life and spirit. A sense of mutual dependence and family interest pervades the cottage group. This under wise direction by the head of the cottage develops into an *esprit de corps*, which is the strongest factor in the cottage system. In a central kitchen all of this is wanting.

Since everything must be done on such a large scale, the food supplies, utensils, cookers, range fixtures, etc., are so heavy that but little opportunity is afforded for the training of children in such a kitchen. As to the food, quantity rather than quality is the factor most in evidence. Refinements of the culinary art are wanting. There is an absence of variety. There can be no catering to individual or group tastes. Such a kitchen cannot serve as a school. In the immense dining rooms of such institutions the children do not partake of their meals with refined table manners and social intercourse—they are simply fed.

Education.—The education of orphans and dependent children in institution homes up to within very recent years has been so meager that but little can be said in its favor. Many of those established by the various religious denominations have been administered along narrow sectarian lines. Children are retained until twelve or fourteen years of age and then either returned to relatives or placed out in family homes, where they become in most instances the unpaid servant of the household.

Most of the orphanages have maintained their own schools and in these the teachers and instruction are inferior to the standards of the public elementary schools. The teachers are usually required to perform other services in the institution in addition to the work of teaching. The course of study leads nowhere and there is no higher school beyond the institution school to awaken an ambition for promotion. Rarely have the children in such homes passed beyond the elementary grades while remaining in the institution. After their release to relatives or private homes, subsequent school attendance becomes desultory or is entirely abandoned. This has been the experience of scores of thousands of orphans and dependent children. As conceived by most of the managers of homes for dependent children, charity was to go no further than was necessary to enable the child to earn his keep when placed in a family home. The uncertain and transitory period of his stay in the institution made school attendance largely a matter of marking time rather than an experience of purposeful effort. The more recent and enlightened view, however, regards makeshift school attendance and such early exploitation of child life as not only an individual but a social waste. Much more extended educational advantages are, therefore, now being provided by the more progressive institutions in this country. A few of the better class are sending their wards to the public schools, and children of educational promise are given an opportunity to pursue secondary and in some cases even higher educational courses. There has also been great progress in education along industrial lines. Some of the institutions now provide special teachers in manual training, cooking, dress-

making, etc. The institution's own needs in these fields of instruction give a much more practical turn to the work than is possible in public school instruction. Thus, in the sewing and dressmaking classes the girls repair and make garments for themselves and other children. In the manual training classes the boys repair and make new furniture, toys, play apparatus, and implements for their own use in work about the place. In the garden and poultry classes they raise vegetables and poultry for their own tables, and the cooking classes frequently prepare the regular meals of the cottages.

Since the institution furnishes not only the school, but also the child's home life and environment, it is possible through correlation to bring these two into very close touch in the classroom. The everyday interests and activities of the child may not only interpret the subject matter of the classroom, but may also furnish much of the educative material itself. The course of study may be adapted at every turn to the experience and interests of the child. Every important event or development in the life of the home, plowing, planting, cutting down trees and sawing them into lumber and cord wood, starting and running incubators and brooders, buying and selling, building and paving, incidents and accidents,—all are fraught with educative stuff.

There is another important aspect in which the institution school can adjust itself to the needs of the child and where the public school fails to meet a condition. As children move upward through the grades the subject matter of instruction grows more and more abstract, while the child in the earlier years of the adolescent period, the years of physical stress and rush, unless naturally studious or academic in his tastes, yearns for concrete experience, for action, for industrial work, economic gain, and freedom from physical restraint. In the institution he may give half of each day to industrial work and the other half to school work, thus preserving a balance that may tide the child over a restless period of a year or two and still preserve and keep alive and going those academic interests which ordinarily are lost forever to the pupil that drops out of the public school during this period.

But most of the institutions of the country have not risen to their educational opportunities. The above conception of education is realized in but few of the more progressive ones. Many of them, however, are in a state of transition. They are moving from urban to rural locations and changing from congregate to cottage systems of housing. Along with these changes improvement in educational standards and methods is keeping pace. Hitherto this progress in education has been greatly retarded by the fact that they have been regarded as homes rather than schools. Since the meaning of childhood is gradually

being interpreted more and more in terms of education, institution life is passing into a renaissance of higher training, intellectual, industrial, and social. R. R. R.

ORR, GUSTAVUS ADOLPHUS (1819-1887).—State Superintendent of Schools, was educated in private schools, at the University of Georgia, and at Emory College, graduating at the latter in 1844. He taught in Georgia and Tennessee from 1845 to 1849; was instructor and professor in Emory College from 1849 to 1867; was president of the Southern Female Masonic College from 1867 to 1871; one year professor in Oglethorpe University; and from 1872 to his death in 1887, he was State Commissioner of the Schools of Georgia. He is called the father of the common school system of Georgia. W. S. M.

ORTHOGRAPHY.—See **SPELLING**.

ORTHOPEDIC INVESTIGATIONS AMONG SCHOOL CHILDREN.—See **CRIPPLED CHILDREN, EDUCATION OF; SPINAL CURVATURE; etc.**

ORTON, JAMES (1830-1877).—Scientist and college professor; was graduated from Williams College in 1855, and from the Andover Theological Seminary in 1858, after which he traveled and studied in Europe. He was for several years pastor of a Congre-

gational church. From 1866 to 1869 he was professor of biological science in the University of Rochester, and from 1869 to the time of his death at Vassar College. He conducted several scientific expeditions to the high Andes, and met his death on such an expedition at Lake Titicaca Besides numerous scientific works, his publications include *The Liberal Education of Women* (1873) and *Comparative Zoology* (1875). W. S. M.

OSORIO (DA FONSECA), JERONIMO (1506-1580).—Bishop of Silves in Portugal; studied in the universities of Salamanca, Paris, and Bologna, and became Professor of Divinity at Coimbra (*q.v.*). Osorio is called the Cicero of Portugal One of Osorio's treatises, the *De Gloria*, was thought by some of his contemporaries to have been a lost work of Cicero, found and published by Osorio. Osorio's chief educational work was the *De Regis Institutione et Disciplina, Libri VIII* (Colonix Agrippina, 1572). It is a book of great length, praising the seven liberal arts, grammar, dialectic, and rhetoric, with arithmetic, music, geometry, and astronomy, all of which a true king will well know. But more urgently still are the moral virtues of a king extolled—prudence, wisdom, temperance, justice, magnanimity, and so on. Osorio is praised because he writes in a series of reasonings rather than grounds himself mainly on quotations, a method common in his time. Roger Ascham (*q.v.*) speaks in his praise (see *Scholemaster*, pp. 129-131. Mayor's ed., 1863).

F. W.

OSWEGO MOVEMENT.—A systematic attempt, radiating from the State Normal School at Oswego, N. Y., to introduce the best features of Pestalozzianism into the schools of this country. The spirit of the movement was inseparably bound up in the life of its founder, Dr. Edward Austin Sheldon (*q.v.*). Lake Pestalozzi, Dr. Sheldon was first led to take an interest in education by observing the condition of the poor children of Oswego. As early as 1848 he had organized a school for them and was trying in various ways to ameliorate their condition. After this philanthropic experiment, Dr. Sheldon spent nine years in public school supervision, first at Syracuse and later at Oswego. The result of his experience was a deepening conviction that not only had we failed to give universal education, but that the methods of teaching then in vogue were unscientific and the course of study was too narrow and formal. He then resolved to devote himself to the reform of education, which proved to be his lifework. Dr. Sheldon saw clearly that the first step toward bettering the schools was to secure

better-trained teachers. To this end for a time he carried on Saturday classes for teachers at Oswego and gave instruction in the principles of teaching. In order to supplement with practical work, the school board of Oswego cooperated in establishing a city training school, selecting a sufficient number of their public schools to be used as model or practice schools. In the same year (1861) Miss Margaret E. M. Jones was persuaded to come from London to teach in the new school. Miss Jones had taught for fifteen years in the Home and Colonial Training School. (See HOME AND COLONIAL SCHOOL SOCIETY.) Miss Jones remained at Oswego only one year, but that served to place upon a firm footing the essential ideas of the great Swiss reformer. The object-teaching phase of his work seems to have appealed strongly to his English followers, and as might have been expected, Miss Jones emphasized object lessons as a separate branch. But it should be noted that Dr. Sheldon had been previously much impressed with the large collection of objects in the Educational Museum of Toronto. The idea of this collection was borrowed from English reformers. The responsibility for the spread of object teaching must also be shared with N. A. Calkins, who was a pioneer in this movement.

After Miss Jones withdrew from Oswego, Dr. Sheldon had the good fortune to secure the services of Herman Krusi, Jr. (*q.v.*), the son of Pestalozzi's most famous assistant. His entrance into the Oswego group helped to call public attention to this new center of educational reform. Of the other teachers whose devotion helped to make the Oswego work a distinctive movement, Dr. Sheldon's daughter, Mary (the wife of Professor Earl Barnes), must be named. Her well-known methods of introducing children to the study of history by beginning with the sense phases of local history is a practical and valuable application of Pestalozzi's maxims.

The work done at the city training school at Oswego was so radically different from the general routine that it soon roused the active criticism of those who honestly investigate new movements hoping to find something good, and the hostility of those who oppose all progress. The findings of the former class were so favorable that the training school was first assisted by grants from the state, and in 1866 the school was taken over by the state and made one of the regular state normal schools of New York. For many years the school continued to send out teachers trained to put into practice more or less skillfully the maxim "that the primary concepts of all branches of knowledge come through the senses." These teachers were in demand for training schools and as supervisors of primary work throughout the country. The teachers who had grasped the meaning of their Oswego

training realized that sense-perceptions must be elaborated by other forms of mental activity, and provided for this in their teaching. On the other hand, in some cases the Oswego methods sometimes degenerated into a mere giving to children masses of unrelated facts about miscellaneous objects, which did much to discredit efforts to find any better ways of teaching children than by formal book study. In spite of these failures the Oswego movement was a powerful factor in creating a general demand for trained teachers, in enriching the content of instruction in elementary schools, in promoting more scientific methods of teaching, and in making more easy and effective later educational reform. OTTAWA UNIVERSITY, OTTAWA, KAN.—Founded in 1886 and conducted by the Baptist denomination of that state. The institution grew out of missionary work for the Ottawa Indians, and for a time was attended by both races. Later the institution was organized for the whites only, the first college graduation being in 1886. In 1912, 440 students have been graduated, the collegiate student body numbering 165, the preparatory about 100. The physical plant consists of thirty acres of campus and four buildings. The annual budget is about \$30,000 in almost equal amounts for fees and endowment funds. The faculty consists of ten members.

OTTAWA, UNIVERSITY OF, TORONTO, CANADA.—Founded in 1849 by the Oblate Fathers of Mary Immaculate as the College of Bytown. In 1866 it received the present title and power to confer degrees. In 1889 it was raised by the Pope to the rank of a Catholic University. The following courses are given by the university: preparatory or general (three years); commercial (two years); collegiate (college entrance); arts (four years, leading to B.A. or B.L.); law (three years, leading to LL.B.); philosophical; theological (four years). The large majority of students are enrolled for pre-college courses.

OTTERBEIN UNIVERSITY, WESTERVILLE, OHIO.—The institution, founded in 1847, is located twelve miles from Columbus. It is nonsectarian in its teaching, but under the control of the church of the United Brethren in Christ. It is coeducational, having been one of

the first colleges in America to grant equal privileges to men and women. The University maintains a college, an academy, music and art departments. A strong summer school is conducted. There are seven buildings and forty acres of campus. The total assets (1911) were \$418,591.11. The student attendance was 486, of whom 214 were in the college department. There are seven groups of studies leading to degrees in the college. The teaching staff consists of twenty-seven professors and instructors on full time and pay.
W. C. C.

OUACHITA COLLEGE, ARKADELPHIA, ARK. — A coeducational institution established in 1886 under Baptist auspices. Preparatory, collegiate, business, music, and fine arts departments are maintained. The entrance requirements are fourteen units. Bachelor degrees in arts, science, literature, and music and the degree of Master of Arts are given. The faculty consists of thirty members. The enrollment in 1911-1912 was about 370 students.

OUGHTRED, WILLIAM (1575-1660). — Clergyman and teacher of mathematics, the son of the scrivener of Eton College, who also taught arithmetic. The boy became a King's Scholar of Eton, and in 1592 entered King's College, Cambridge, where he gave much attention to mathematics, and in his twenty-third year wrote his *Horologigraphia Geometrica*. Foreign mathematicians came over to England to converse with him, and English mathematicians like Seth Ward and Charles Scarborough, John Wallis and Christopher Wren, the architect, came to him as pupils, and he was in touch with the chief mathematicians of his period. Any that wrote an "ill hand," he taught writing, and himself "drew his schemes most neatly, as if they had been cut in copper." He was an astrologer, and "very lucky" in this study. Nicholas Mercator, the geographer, was one of his friends. Further, Oughtred was a "great lover of chemistry," and of heraldry. Oughtred had received a classical training and turned it to account in reading all the ancient authors in mathematics, — Euclid, Apollonius, Archimedes, Diophantus, etc., — whom he read both inquiringly and critically. At Cambridge he invented an easy method of geometrical dialing, translated from English into Latin in 1647 by Mr. (afterwards Sir) Christopher Wren. He projected a horizontal instrument for delineating dials upon any kind of plane, and for working most questions which could be performed by the globe. Oughtred's enthusiasm for the study of mathematics was equaled by his love of teaching, which is shown by the fact recorded by Aubrey: "He taught all free." His most famous book was the *Arithmetice in numeris et speciebus In-*

stitutio: quæ tum logicæ, tum analyticæ, atque adeo totius Mathematicæ, quasi Clavis Mathematicæ est, London, 1631. Other editions were numerous. Oughtred also wrote on the *Delineation of Sundials by Geometry*, 1647; the *General Horological Ring and Double Horizontal Ring and Double Horizontal Dial*, 1653; on *Spherical Triangles*, 1657, and *Trigonometria*, 1657.

OUTLINES, TOPICAL. — The topical method of study finds its most intense application in the use of topical outlines by means of which a rigid control is kept over the study of pupils, as the subtopics that develop the main topics are strictly laid down. Inasmuch as the outlines usually represent a mature reflective view of the subject rather than the genetic view characteristic of the beginner's advance from ignorance to knowledge, the use of the outline tends to curtail independent thought upon the part of the child, and to encourage the memorization of facts about the various topics. Usually the child's interests are little considered in teaching from an outline and the instruction is therefore less vital. The use of the topical outline has the advantage of being definite, and eliminative of waste effort. When the topics are in the form of questions or problems arranged in real psychological sequence rather than in the form of abstract headings, teaching from a topical outline is less artificial. Such a study from outlines is less frequent now than several decades ago. It is used more particularly with grammar grade and high school students than with primary and intermediate pupils. Its successful use depends upon the maturity of the students. It is hardly used in arithmetic and the language subjects, and considerably employed in geography, science, literature, and history. It is most largely utilized in the teaching of history.

OVER-AGE. — See RETARDATION AND ELIMINATION.

OVERBERG, BERNARD HEINRICH (1754-1826). — A German ecclesiastic and edu-

cator, was born of poor parents in the Diocese of Osnabrück and was educated for the priesthood at Münster, Westphalia. Having been ordained priest in 1780, he was appointed in 1783 to direct the Münster Normal School, a summer school for Westphalian teachers. This work he continued during forty-three years. As the province had at that time no teachers' seminary, this course offered the only opportunity for the training of teachers, and Overberg's work was of great value. The *General School Regulation for the District of Münster (Allgemeine Schulverordnung für das Münsterland)*, promulgated in 1801, regarded at that time as a model school law, was practically Overberg's work. His *Anweisung zum Schulunterricht (Directions for School Instruction)*, first published in 1793, is still used, a new edition appearing in 1903. At the time of its first appearance the book was translated into French and commended even by Protestant educators. Among other books which he wrote for the schools may be mentioned his *Primer (Neues A-B-C, Buchstabil- und Lesebuch für die Schulen Münsterlands, 1788)*; *Biblical History (1799)*; and the *Catholic Catechisms (1799 and 1804)*. OVERPRESSURE (German *Überbürdung*).

—A somewhat vague and general term for alleged overwork in the school. A great variety of opinions prevails in regard to the matter. Teachers and educators are apt to feel that there is little, if any, overpressure in the schoolroom except upon the teachers. Physicians, on the other hand, often strongly condemn the school for overworking the pupils and are ready to cite many cases of overpressure. Some thirty years ago there was a very strong protest against overpressure in the schools in Germany and several other European countries, especially in the higher schools. The complaint on this score has apparently been much less during the last one or two decades; and among educators many voices have been heard in protest against the danger of making pupils effeminate and self-conscious in regard to matters pertaining to their health by the great amount of attention given to school hygiene and the like.

Amid this confusion of opinion certain facts are significant and may be briefly enumerated. First, the length of the school period, the hours for beginning and closing school, the

time devoted to recesses, the amount of home study required, the holidays and vacations, and the kind and amount of school work demanded, vary greatly in different countries. Again, what may be a perfectly normal amount of work for ordinary healthy children may be altogether too much and a source of serious overpressure in case of the weak and defective. Investigations in many schools in many countries have now shown that, without taking account of diseases of the teeth, from 30 to 50 per cent of the children in any school are more or less handicapped by some defect or disease. Among this group of children a large number are liable to overstrain from an amount of work that is quite reasonable for the remainder of the class. It frequently happens also that the defects of these children are not known by their teachers and injustice is done to them on this account. (See MEDICAL INSPECTION IN SCHOOLS.)

Further injustice is done by the improper grading that exists in many schools. With the ordinary classification according to chronological age and scholastic attainments, many of the children in the same class may be at a lower stage of physiological and psychological development, and hence lacking in the ability to do the amount of work that may rightly be given to other children in the same class who are of the same chronological age but of greater physiological and psychological maturity. (See GRADING AND PROMOTION; GROWTH.)

Another significant fact is the varying amount of extra-scholastic occupations engaged in by the pupils,—among the boys the selling of papers, doing errands, helping in the home work and the like; among the girls the care of other children, domestic duties, and special lessons in piano playing, dancing, etc.; and in case of both girls and boys the entertainments, parties, meetings, and the like, that are attended. It is often just because children come to school handicapped by the fatigue from outside duties or outside dissipation that it becomes necessary for special hygienic care in connection with the school work.

Statistics in regard to school diseases, fatigue, eye defects, etc., have often been cited to show the overpressure in the school. Few, if any, of these have given satisfactory evidence of overpressure in the school as a cause; but they do show that with so many cases of defect and disease there is likely to be overpressure, as a result, and that there is need of special care for the proper hygiene of instruction. In many cases also conscientious pupils, by the suggestion of ambitious teachers or parents, or the factitious stimulus of examinations (*q.v.*) and marks, not infrequently work for a cruelly long period. The older investigators found pupils in the Swedish, Danish, and German schools working ten or

twelve hours a day, and inevitably spending too little time in sleep and recreation. While statistics are inadequate and often misleading, observation shows that at the present time many individuals work for an unreasonably long period in the schools in this country. Especially is this likely to occur at the time of examination and in what are supposed to be the especially important periods of school life, the ninth grade and the last year in the High School. As Dr. Dukes, the school physician at Rugby, has pointed out, we have laws against working a child's body for long hours, but there is no law to forbid working a child's brain to the limit of endurance.

Among teachers there is undoubtedly a great amount of overpressure. The nervous strain from instruction and discipline, the time spent in keeping school records, in correcting exercises and examination papers, and in preparing for special lessons, and often in the visiting of pupils in their homes, and in many cases the worry over meeting the demands of the authorities higher up and of holding one's position, not only cause many breakdowns among the teachers themselves, but the weariness of the teacher is pretty apt to react upon the pupils and becomes an important factor in mental overpressure in the school. The most immediate remedy would seem to be less red tape, a better system of grading, and the allotment of a smaller number of pupils to each teacher.

Consideration of the facts cited shows clearly that there is often danger of serious strain in the case of individual pupils, and the points to be emphasized for the avoidance of overpressure are the following: (1) Physical and mental examination of all pupils at the entrance upon school life, and periodic tests thereafter. (2) The need of a better system of grading, based upon physiological and psychological age, rather than upon chronological age and school attainments, and upon the conditions of physiological and psychological health and ability to work. (3) A better training of teachers in school hygiene so that proper care may be given to children who suffer from physical and mental defects. (4) A better distribution of the period of study, with more time for recess, better arrangement of the work, and the like, with due regard to the teaching of modern hygiene as to fatigue, the need of alternating periods of work and rest, and economical methods of learning. (5) Care in allotting of home tasks, the explanation of lessons when assigned, the abolition of school tasks as punishment, shorter examination periods and less stress upon the results of examinations, and a general regard for the obvious teachings of mental hygiene and the hygiene of instruction. (6) A smaller number of pupils to each teacher.

OVERSTUDY. — See OVERPRESSURE.

OVERWORK. — See FATIGUE; OVERPRESSURE IN THE SCHOOLS.

OVID. — P. Ovidius Naso, the "laureate of the gay society" of the later Augustan period, has been, next to Vergil, the most widely read and most widely imitated of the Roman poets. Associating intimately, perhaps too intimately, with the decadent men and especially women who composed the circle of Augustus's profligate daughter Julia, he devoted himself almost exclusively to erotic poetry (*Amores*, *Heriodes*, *As Amatoria*, *Remedium Amoris*), written in the elegiac measure, in the mastery of which he has never been surpassed. After recovering from the dismay inspired by Julia's disgrace and banishment in B.C. 2, Ovid turned his attention to story-telling, for which his gay and unstable genius was particularly well fitted. As his subject he chose the legends of the Greek pantheon and wrote fifteen books of Transformations (*Metamorphoses*), embodying the mythology of the ancient world from chaos to the deification of Cæsar. He also composed a poem on the Roman calendar (*Fasti*), diversified by stories of early Roman legend but before he finished it he was suddenly, without warning or explanation, exiled by Augustus in A.D. 8 to Tomi, a savage place on the Black Sea, where after unavailing lamentations (*Tristia*) and letters (*Ex Ponto*), he died in A.D. 17 or 18.

The *Metamorphoses* has been the great ancient storybook for ages. While many of the stories are unsuitable for children, yet a large number are beyond criticism, and the charm of the style, the comparative ease of the narrative, and the smoothness of the meter render a selection from these tales an admirable

book with which to begin the study of Latin poetry, and thus lead up to Vergil. Consequently, where the curriculum admits of it, some selection from the *Metamorphoses* is frequently read after the first extended reading of Latin prose (usually Caesar). When there is more time a few selections from the other poems may be added with profit.

The chief difficulty is the metrical form, the heroic hexameter, which causes such a shift in the ordinary prose order as to greatly confuse the young student. To obviate this, it would be well to rearrange the narrative in the order of prose and this is actually done in some textbooks. For the narrative, the pupil should also have access to Bulfinch's *Age of Fable*, or Gayley's *Classic Myths*. The mysteries of scansion should occupy the pupil but little at this stage, nor should much attention be paid to the influence of Ovid upon English poets. The best collection of material for the study of this influence is found in Miller's *Ovid* (American Book Co., 1910).

There has been no complete edition of *Ovid* with notes since the Variorum edition of 1827 (Oxford). The last complete text edition is by Postgate (London, 1894). Of separate poems there have been numerous modern editions, but those of the *Metamorphoses* and *Fasts* have been confined almost entirely to school books. G. L.

OVIEDO, UNIVERSITY OF, SPAIN. — See SPAIN, EDUCATION IN.

OWEN, ROBERT (1771-1858). — Born in Newtown, Montgomeryshire, Wales; the son of Robert Owen, saddler, ironmonger, and postmaster of Newtown. He was the sixth of seven children and was precocious in the development of his literary and religious interests. He had an early passion for reading, and books were left to him by the clergyman and other residents in the town. He was sent to school at a very early age and began to help his schoolmaster in teaching at the age of seven. He was apprenticed in his eleventh year to a draper at Stamford: "From ten years of age I maintained myself without ever applying to my parents for any additional aid." In 1787 (during the early days of the industrial revolution) he became assistant in the shop of Satterfield, a draper in St. Ann's Square, Manchester. In 1789 he set up as a maker of spinning mules, and quickly showed great business ability.

The second period of Owen's life, 1790-1821, was that of active occupation as a large employer. In 1790 he became a cotton spinner on a small scale in Manchester, subsequently acting as manager of a large cotton mill, and, in 1794, as managing director of the Chorlton Twist Company in Manchester. In 1799 he bought for himself and partners the cotton mills at New Lanark, near Glasgow, belonging

to David Dale (*q.v.*), whose daughter, Anne Caroline, he married in the same year. In Manchester Owen had become the friend of John Dalton and Dr. Percival, and was a member of the Manchester Literary and Philosophical Society, established in 1781. From this group he gained an impulse towards the reform of the factory system and the better education and housing of apprentices and working people. He organized the rough and ignorant factory community at the New Lanark mills (about 2000 people, including 500 children sent from parish workhouses as apprentices) under paternal government, enforcing cleanliness, temperance, and religious toleration. The minimum age for employment in the mills was fixed at ten. Free education was provided for all children from five to ten years of age. The teaching and discipline in the school followed the methods of Joseph Lancaster (*q.v.*). In 1813, Jeremy Bentham and William Allen, one of the founders of the British and Foreign School Society (*q.v.*), became partners in the mill. During the years 1813-1816 Owen wrote *A New View of Society: or Essays on the Formation of Human Character*, in which he thus formulated his fundamental principle: "Any general character, from the best to the worst, from the most ignorant to the most enlightened, may be given to any community, even to the world at large, by the application of proper means; which means are to a great extent at the command and under the control of those who have influence in the affairs of men." The "plastic quality" of child nature would enable society to be "ultimately moulded into the very image of rational wishes and desires." "All poverty and crime are the effects of error in the various systems of training and government." "The end of government is to produce the greatest happiness to the greatest number." National reform was to be based, in Owen's view, on (1) restriction of the drink traffic; (2) maintenance of the national Church, but as an institution without formularies and without any declaration of religious belief; (3) reform of the Poor Law; (4) universal elementary education from infancy: "The infants of any one class in the world may be readily formed into men of any other class." "Every State to be well governed ought to direct its chief attention to the formation of character; and the best governed State will be that which shall possess the best national system of education." The national system of education was to be uniform throughout the United Kingdom, upon non-denominational lines, under the control of the central government, which should provide and support training colleges for teachers and appoint teachers to the schools; (5) "the obtaining regular and accurate information relative to the value of and demand for labour over the United Kingdom." Official

quarterly labor statistics, showing wages and unemployment in each district, were to be published with a view to greater mobility of labor; (6) provision by the Government of works of national utility (roads, canals, harbors, etc.) for employment (at wages less than the average rate of private labor in the district), of those not able to find work in competitive industry.

Owen and his work at New Lanark quickly became famous. In 1814–1815 he pressed for a new Factory Act. In 1817 Owen published a plan for the establishment of industrial communities, self-contained, educationally organized, and self-supporting, upon a cooperative basis, — a new type of social organization, which, in his belief, would gradually become universal. The plan involved a degree of governmental control which was resented by Radical individualists as likely to strengthen the authority of the existing Government. In 1818 Owen visited Switzerland and saw Oberlin, Pestalozzi, and Fellenberg (*q.v.*). In 1819 he estranged public sympathy by a public declaration against Christianity. In 1824 he heard of an estate on the Wabash river in the state of Indiana which belonged to a German colony which had emigrated from Württemberg under the guidance of a Lutheran teacher, Rapp. This society had given the name Harmony to the estate, from which they now wished to move on. In 1825 Owen bought the village, with 20,000 acres, for £30,000. Before his return to England in 1825 he had established a community of 900 people at New Harmony, to which he returned in 1826–1827 and 1827–1828. Difficulties arose in the society and the colonists gradually gave up the principles of communism upon which their brotherhood had been originally based. In 1828 Owen finally broke off his connection with New Harmony, having spent over £40,000 upon the experiment.

In 1829, after long friction with his partners, he withdrew from New Lanark. In the years 1829–1858 he was continuously engaged in propaganda on behalf of cooperation and socialism, devoting his private fortune to the diffusion of his ideas. In 1832 he opened an equitable labor exchange in the Gray's Inn Road, but the new institution survived but for a short time. His activity stimulated the growth of the cooperative movement throughout England, and he never failed to emphasize the importance of education as one factor in economic progress. In 1854–1856 Owen was converted to spiritualism by an American medium. He died at Newtown, the place of his birth, November 17, 1858. Of his three sons, Robert, Daniel, and David Dale, the two last became Professors in American Colleges.

Owen was single-minded, devoted to his fellow men, untiring, indiscriminating; the

spiritual father of a great movement; a prosy saint, successfully unsuccessful; a seer who prophesied, with fatal one-sidedness, one side of the truth of social and educational reform. He was blandly impermeable to the prick of facts; philosophically unphilosophical; scientifically unscientific. He emphasized (1) the importance of social environment in the development of character; (2) the need for an economic structure of society in conformity with a new ethical ideal; (3) the necessity for using capital in the organization of community life; and (4) the value of well-directed education from infancy. But he underestimated the power of heredity; he overlooked the bad side of human nature; he underrated the complexity of the economic structure of industrial society; he exaggerated the power of direct instruction upon character; he was oversanguine as to the practical efficiency of governmental action; and he did not clearly decide whether the ultimate basis of social control is to rest on the majority vote of adult male citizens or upon some enlightened despotism, whether individual or bureaucratic. His persevering but tedious speeches disseminated socialistic ideas, but failed to convince national opinion, which preferred a combination of individual effort and state regulation.

OWENS COLLEGE. — See MANCHESTER UNIVERSITY.

OXFORD CAPS. — See ACADEMIC COS-TUME.

OXFORD COLLEGE FOR WOMEN, OXFORD, OHIO. — The oldest Protestant college for women conferring the B.A. degree in the United States. It was founded in 1830 by President Bishop and Professors Scott and McGuffey of Miami University, a neighboring institution. There have been more than 4500 students, including many women eminent in public life. The institution is one of the few women's colleges of full collegiate grade west of the Atlantic states. Fifteen units are required for entrance and 120 hours of college work for the B.A. degree, seventy of which are specified. The greatest stress is laid upon history, language, philosophy, and music. About 200 students are enrolled each year. The faculty consists of twenty members

J. S.

OXFORD UNIVERSITY. — Origins. — The story which attributes the foundation of a university at Oxford to Alfred the Great is purely mythical and rests chiefly upon an impudent insertion in Camden's edition of Asser *Menevensis*. No schools of any kind or sort can be shown to have existed at Oxford till the beginning of the twelfth century. Somewhere in the decade 1110-1120 Theobaldus Stampensis (*i.e.* of Étampes in Normandy) became a Master at Oxford. His extant works are a short and violent attack upon the monks, (*Improprium contra monachos*), and five letters, in the earlier of which he is described as a "Doctor" or "Master" of Caen, in the later as "Master of Oxford." The *Improprium* provoked a reply in which it is stated that Theobald was teaching "sixty or a hundred scholars more or less" at Oxford. (Migne, T., Vol. CLXIII, c. 759; extracts in T. E. Holland, *Collectanea* (Vol. II, p. 156: *Oxf. Hist. Soc.*). In 1133 we hear of a more famous Master, the theologian Robertus Pullus, as teaching in Oxford. (*Oseney Chron.*, ed. Luard, *Annal. Monast.*, Vol. IV, p. 19). The jurist Vacarius certainly taught Roman Law in England in 1149, and at some time or other taught in Oxford (Rob. de Monte, *Chron.*, ed. Migne, T., Vol. CLX, p. 466; Gervasius, *Cantuar., Actus Pontificum Cant.* ed. Stubbs, Vol. II, p. 384.) It may be that the Oxford teaching was as early as 1149, though there is some reason for suspecting that it was later. These are the only allusions to schools at Oxford before the year 1167. Soon after that date — but not before — we find Oxford

blossoming out into what a little later came to be known as a *Studium Generale*, *i.e.* a place of study which attracted students from distant regions. At about that date Henry II, then engaged in deadly conflict with his rebellious and exiled Archbishop, Thomas Becket, ordered that all clerks then resident abroad should return to England, "as they love their benefices" (*Materials for the Life of Becket*, ed. Robertson, I, 53); and a contemporary tells us that "the king wills also that all scholars be compelled to return to their country or be deprived of their benefices" (*l.c.* VII, 146). John of Salisbury likewise informs us of a certain old prophecy that the "Mercuriales" (*i.e.* scholars) should be depressed, which had now in the year 1167 been fulfilled, for the "Mercuriales have been so depressed that France, the mildest and most civil of nations, has expelled her foreign scholars" (*l.c.* VI, p. 236). This may refer to some action on the part of the French, or it may be a rhetorical way of expressing the effect of the English king's edict. Taken together, these passages make it clear that somewhere about 1167-1168 there must have been a great exodus of English scholars from Paris, which was then the usual place of higher education for Englishmen, and others would be prevented from going to Paris for the first time or from returning after the long vacation.

It was the wont of medieval scholars, when a quarrel with the authorities or the townsmen or other untoward events prevented their continuing their studies in one place, to transfer themselves, with whatever in the way of scholastic organization they possessed, to a more hospitable city. Most of the older Universities of Europe — except the few great Mother Universities — were founded by scholastic migrations of this kind. It may be treated as certain that somewhere in England — at one place or at more than one — a *Studium Generale* would grow up in consequence of this exodus from Paris. As a matter of fact, we hear of nothing entitled to the name of a *Studium Generale* anywhere in England but at Oxford; at Oxford we do hear of such an institution within a few years after the migration of 1167-1168, but not before those years. At about this date we begin to hear of scholars coming to Oxford from distant regions, the names of "writers," parchment makers, and illuminators begin to multiply in deeds relating to Oxford property, and sermons were preached expressly for "clerks from various parts of England." (Thomas Saga Erkebyskups, ed. *Materials*, II, p. 99; Rashdall, *Universities of Europe in the Middle Ages*, Vol. II, p. 342 sq.) In 1184 or 1185, Giraldus Cambrensis tells us that he read his *Topographia Hibernica* to "all the Doctors of the different faculties, and such of their pupils as were of greater fame or note"; and on another day to "the rest of the scholars" (ed. Brewer, Vol. I, pp. 72,

73). In 1190 a student of the low countries at about the age of twenty crosses the sea to study the liberal arts at the *commune* (i.e. *generale studium litterarum* at Oxford (*Emonis Chron.*, ap. Pertz, *Mon. Germ. Hist.*, xxiii, p. 467); while in the year 1209 an event occurred which reveals the existence, according to a contemporary estimate, of 3000 students at Oxford.

This was the period of the great quarrel between King John and the clergy. The realm was under an interdict; the King was excommunicated or threatened with excommunication. At such a time it went hard with clerks who quarreled with their lay neighbors. The murder of a woman by a scholar led to a violent "town and gown" riot of the kind habitual in all medieval universities, and two or three of the scholars were hanged by the townsmen with the consent of the King. Matthew Paris (*Chron. Maj.*, ed. Luard, Vol. II, pp. 525-526, 569) tells us that 3000 scholars left Oxford, and resumed their studies elsewhere—some at Cambridge, others at Reading. The town remained almost destitute of scholars till 1213, when John's submission to the Pope compelled the townsmen of Oxford to humble themselves before the ecclesiastical authorities. The ordinance issued by the Papal Legate in 1214 constitutes the first official recognition of the University which has come down to us. (*Munimenta Academica*, ed. Anstey, pp. 1-4.) The actual offenders were to do penance by marching in procession, barefoot and without coats, to the grave of their victims, followed by the whole body of townsmen, and were then to escort the bodies to the cemetery for the solemn ecclesiastical burial which had apparently been denied to them. The town was for ever to pay forty-two shillings a year to be expended on a feast of bread and beer, pottage, and meat or fish to a hundred scholars. In future, a clerk arrested by the town authorities was to be surrendered on the demand of "the Bishop of Lincoln or the Archdeacon of the place or his official or the Chancellor, or whomsoever the Bishop of Lincoln shall depute to this office." This is the first mention of the Chancellor of Oxford. He is subsequently spoken of as "the Chancellor whom the Bishop of Lincoln shall set over the scholars therein." These words seem to indicate that no Chancellor had yet been appointed or at least officially recognized.

Early Organization.—As to the organization and government of the University prior to the year 1214, we are left wholly to conjecture. It is probable that the Masters and scholars who transferred themselves from Paris to Oxford in the time of Henry II would reproduce at Oxford what organization already existed at Paris. A *consortium* or company of Masters is known to have existed in Paris at about this date (1170), and we may

therefore assume that from this time a rudimentary "University" or gild of Masters existed in Oxford; but at Paris—and, therefore, it may be presumed, at Oxford—the organization was of the most elementary description. The gild, in all probability, had no officers of its own, no written statutes, no common seal. The Masters held meetings for the purpose of admitting new members, already licensed by the Chancellor of the Cathedral, to their society by the ceremony of inception (*q.v.*) by which they were held to become full Masters. At Oxford there was no Cathedral or Collegiate Church from the Chancellor of which the Masters could obtain their *licentia docendi*. How the licenses were granted prior to 1214 we do not know; possibly they were granted by the Archdeacon, or the Masters may have ventured to grant licenses themselves, or to elect a Master who may have been called *Rector Scholarum* (a title said to have been borne by Robert Grosseteste (*q.v.*), subsequently Bishop of Lincoln, it may be before 1214, *Lincoln Reg. Sutton*, f. 117), or he may even have been popularly known as Chancellor. At all events, when the Chancellorship came into existence, it was clearly an attempt to reproduce the Parisian Chancellorship, in so far as it could be reproduced without a Cathedral chapter. The Chancellor was the Bishop's educational officer; he granted the license and exercised an extensive ecclesiastical jurisdiction over Masters and scholars—a jurisdiction which was constantly extended throughout the medieval period by successful charters or concessions from King, Pope, or bishop. From the first, the absence of a chapter placed him in very different relations to his scholastic subjects from those which obtained at Paris. At Paris the Chancellor was a member of a hostile corporation; his rule was violently resisted by the scholars; their gild or University grew into corporate existence very largely as a means of emancipation from his authority. At Oxford the Chancellor was—possibly from the very beginning—elected by the Masters themselves out of their own body. He was the instrument and the representative of their privileges and exemptions from ordinary jurisdiction. Under these circumstances the University required no other head. He soon became, if he was not from the first, the recognized head of the University as well as the Bishop's representative and judge. He may be described as the Parisian Chancellor and the Parisian Rector rolled into one, and something more. His authority grew as rapidly as that of his Parisian prototype diminished, and he gradually became more and more independent of the authority which he nominally represented. The necessity of the episcopal confirmation was abolished by papal authority in 1368 (Wilkins, *Concilia*, Vol. III, p. 75); and in 1395 he was exempted from all episcopal

and archiepiscopal authority (*Mun. Acad.*, p. 78; Wood, *Annals*, Vol. I, p. 365).

The growth of the University's internal organization followed in the steps of the Parisian development — always with the enormous modifications required by the different position of the Chancellor. The University, as at Paris, was divided into the Faculties of Theology, Law (here Civil as well as Canon Law), Medicine and Arts. But the superior Faculties had little organization of their own; they never possessed Deans. The Masters of Arts were for a time divided into Nations. We first hear of the Proctors in 1248 (*Mun. Acad.*, p. 777). At first, there is some reason to believe that there were four Nations and four Proctors (sometimes called "Rectors or Proctors"), as at Paris. But from an early period there were but two Nations, the Southern (*Australes*) and the Northern (*Boreales*), each with one Proctor. The Welsh, Irish, and continental students were included in the Southern, the Scotch in the Northern, Nation. And after a great faction fight in 1274 it was solemnly resolved that there should be only one Nation at Oxford (Doc. in *Archives*; Rashdall, Vol. II, p. 369). There continued to be a Southern and a Northern Proctor, but the Faculty of Arts debated and voted as a single body, jointly presided over by the two Proctors. No Rector was required at Oxford, for meetings of the whole University were presided over by the Chancellor, but, just as at Paris the Rector of the Artists passed by imperceptible stages into the position of Head of the whole University, so the two Oxford Proctors — originally the representatives of the Regent Masters of Arts, became the executive, under the Chancellor, of the whole body. As at Paris, the voting in the University Congregations was "by Faculties," the Non-regent Masters of Arts here forming a separate "house" with the four Faculties, and a majority of the five bodies was ultimately considered to bind the whole University. Thus in the fully developed Oxford Constitution there were three distinct Congregations or Convocations: (1) the Great Congregation (to which the name of Convocation was eventually reserved), consisting of the Regent (*i.e.* actually teaching) Masters of all Faculties, and the Non-regents, (2) the Congregation of Regents (in all Faculties) which met, from about 1327, in the Congregation-house, adjoining St. Mary's Church; (3) the "lesser," "previous," or "black" Congregation, consisting of Regent Masters of Arts alone, which met in the now demolished Church of St. Mildred's, summoned and presided over by the two Proctors. Permanent statutes had to be first promulgated in the Black Congregation; at one time the Artists contended that their veto was fatal to further progress, but by the fifteenth century it had been established that promulgation in the Black Congregation

was enough, even if the Regent Masters of Arts voted against the Statute. This complicated Constitution lasted throughout the Middle Ages, and, indeed, — with some small changes in the sixteenth century, — till it was superseded by the code of statutes imposed upon the University by Archbishop Laud. The Black Congregation has left behind it a curious relic in the power still legally possessed by the two Proctors, but hardly exercised except on two historic occasions in the nineteenth century, of vetoing a resolution of Convocation, this was the Laudian substitute for their ancient power of stopping a Statute by refusing to summon the Black Congregation.

University and Town. — It would carry us beyond our limits to attempt to trace the successive steps by which the University acquired first independence of, and then a virtual supremacy over, the town and its authorities. From the first the students were, as in northern Europe generally, treated as *ipso facto* clerks and enjoyed the usual clerical immunities from the jurisdiction of the ordinary courts. In 1231 the Chancellor was allowed to use the town prison over the North Gate — facetiously known as Bocardo, that being the technical name for a mood in the scholastic logic which it is peculiarly difficult to "reduce" or get out of — for the confinement of refractory clerks (*Letters of Henry III.*, ed Shirley, Vol. I, p. 399). A royal charter of 1244 (Ayliffe, *Ancient and present State of the University of Oxford*, App., p. vi) recognized his jurisdiction in all actions of debt or "contracts of moveables" in which one party was a clerk — a jurisdiction extended to all personal actions in 1275 (*Rot. Pat.*, 3 Edw. I, m. 6). The most famous of all "town-and-gown" riots — "the slaughter" of St. Scholastica's Day, in 1354, which may be described as a pitched battle fought with swords and bows in the streets of Oxford for two days, ended in the defeat of the University and the killing of many scholars (Authorities mentioned in Rashdall, Vol. II, p. 405.) The University actually thrived on its misfortunes, and the great charter of 1355 (*Rot. Chart.*, 29 Edw. III, m. 5) condemned the Mayors, Bailiffs, and sixty burghers of Oxford annually to appear at St. Mary's Church to cause a high mass to be said for the souls of the victims, and each to offer a penny on the altar to be divided between the curate and certain poor scholars. A communion and sermon being substituted for mass at the Reformation, the observance lasted till 1825 (Cox, *Recollections*, p. 112). At the same time, the Chancellor's jurisdiction was extended to all cases both civil and criminal in which one party was a scholar — except cases of treason, felony, and "mayhem." The jurisdiction of the Chancellor's court still remains unimpaired as regards civil causes, and in an attenuated form in criminal cases. Besides these privileges, the University long

retained a considerable share in the policing and general government of the town. Till 1868 the "night police" — which represented the ancient "watch" — remained under the control of the University proctors; and the University still sends representatives to the City Council.

Secessions. — Disputes with the City or internal feuds in Oxford as elsewhere led to secessions, sometimes of considerable duration, but none of them — after the foundation of Cambridge — leading to permanent Universities. Northampton (1228, 1263), Salisbury (1238–1278), and Stamford (1334) were the chief scenes of these secessions (Rashdall, Vol. II, p. 395 sq.). An oath binding incepting Masters not to lecture in Stamford continued to be taken by B.A.'s till almost within living memory.

Halls and Colleges. — As in other medieval Universities the usual method of living — except for the wealthy noble who resided with a numerous retinue in a house of his own, and the poor "Chamberdekyne" who lodged with a townsman — was for a party of scholars to hire a house (at Oxford usually known as a "Hall" or "Inn"), employ their own servants and divide the cost of living among themselves. One of the party, known as the Principal, gave security for the rest and presided over the establishment, but the Principal was at first — at least nominally — elected by the community which formed a self-governing society, making its own "statutes," administering its own funds, and in the last resort controlling its own discipline. But the supervision of the University gradually extended itself to the internal affairs of the Halls and rendered the authority of the Principals more and more independent of their subjects, although they continued to be nominally elected by the students even after; in the 16th century, the real nomination passed to the Chancellor. A code of statutes made by the University for the government of the Halls certainly existed by the second half of the fifteenth century, if not earlier, and in 1432 the University insisted that the Principal of a Hall should be a graduate (*Mun. Acad.*, p. 307). The Colleges were at first simply endowed boarding houses for poor scholars. They provided only for members of the foundation, and had nothing to do with the education of these: all resorted to the public schools for their lectures — lectures given by the "Regent" Doctors or Masters, and in part, especially in the higher faculties, by Bachelors who were at the same time pursuing their own studies. At Oxford the colleges were chiefly intended for Masters, or at least Bachelors, of Arts who after finishing their course in Arts required pecuniary assistance to enable them to enter upon or continue the long course in one of the "superior Faculties," especially in the un lucrative Faculty of Theology. The earliest of these foundations —

as regards the date of its founder's bequest — which came to be known as "the Great Hall of the University" or (later) University College — was a very simple affair: a provision for two or more Masters of Arts studying theology, founded by William of Durham, who died in 1249. But it was not till 1280 that the Hall really came into existence, and then the endowment was only equal to the maintenance of four Masters. By this time two other colleges had come into being, viz a small foundation for Artists, supported from about 1261 by John de Balliol, Lord of Barnard Castle, as a penance for having "unjustly vexed and enormously damaged" the Church of Tyne-mouth and the Church of Durham (Matt. Paris, *Chron. Maj.*, ed. Luard, I, 528), — subsequently turned into a permanently endowed institution by his widow Dervorguilla (1282), — and the much more elaborate community known as Merton College, founded by Walter de Merton, Bishop of Rochester, in 1263 or 1264. The "rule of Merton," a body of Statutes given to the College in 1263 and amended in 1270, was imitated by later founders, and permanently fixed the type of the English College. The leading note of the College, as contrasted with some Continental colleges, was its complete autonomy. The only external authority which could meddle with its affairs was the Visitor — in the case of Merton, the Archbishop of Canterbury. The scholars elected their own Warden and other officers, filled up their own ranks, and controlled the management of their own property. A small body of "poor boys" — still under the instruction of the Grammar-master or in the earlier stages of their arts course — were also supported by the foundation, but took no part in its government. This distinction was followed in other colleges, and eventually the name "Fellows" (*socii*) came to be applied to the full members of the Society (usually graduates), while the term "Scholars" was in popular parlance reserved to the inferior foundationers, who began as undergraduates, though the scholarship was often retained till the degree of M.A. was taken. In some cases the ordinary administration of the College was in the hands of a body of senior Fellows, but in nearly all, the youngest full Fellow (after a year of "probation") voted at elections and in some of the more important affairs of the house.

In the next column is a list of the Oxford colleges with the dates of their foundation and names of their founders; the monastic colleges, suppressed at the Dissolution of Monasteries, are bracketed.

Keeble College, founded in 1870 by subscription in memory of John Keeble (*q.v.*), one of the leaders of the "Oxford Movement," and confined to members of the Church of England, is not technically a College of the University, but enjoys practically much the same position.

Balliol . . .	1261-1266	John de Balliol and his wife Dervorguilla (Charter, 1282)	For Artists only: Theological Fellowship added by Sir Philip Somerville in 1340.
Merton . . .	1263 or 1264	Walter de Merton, Bp of Rochester	
University . . (Gloucester)	1280	William of Durham	
(Rewley)	1283	John de Gifford, Lord of Brimsfield	Benedictine.
(Durham)	1280	Edmund, Earl of Cornwall	A Cistercian Abbey
Exeter . . .	1311-1316	Walter de Stapeldon, Bp of Exeter	Chiefly for Benedictine monks of Durham.
Oriel . . .	1324	Adam de Brome; nominally King Edward II	
Queen's . . .	1341	Robert de Eglesfield, Chaplain of Queen Philippa	
(Canterbury)	1362	Simon Islip, Abp. of Canterbury.	Chiefly for Canterbury monks.
St Mary College of Winchester (commonly called New College)	1379	William of Wykeham, Bp of Winchester	
Lincoln . .	1429	Richard Fleming, Bp of Lincoln	
(St Bernard's)	1432	Henry Chicheley, Abp of Canterbury.	Cistercian.
(St Mary's)	1435		For Augustinian Canons.
(St George's-in-the-Castle)	1435		For Augustinian Canons of Osney
All Souls . .	1438	Henry Chicheley, Abp of Canterbury	
Magdalen . .	1448	William of Waynflete, Bp of Winchester	
Brasenose . .	1509	William Smyth, Bp of Lincoln and Sir Richard Sutton.	
Corpus Christi	1516	Richard Foxe, Bp of Winchester	
Christ Church	1532	Henry VIII; previously, as Cardinal College, by Cardinal Wolsey	
Trinity	1554-1555	Sir Thomas Pope	On site of Durham College
St John's . .	1555	Sir Thomas White, Alderman of London	On site of St. Bernard's
Jesus	1571	Queen Elizabeth and Dr Price	
Wadham	1612	Nicholas and Dorothy Wadham	
Pembroke	1624	Nominally James I; Richard Tesdale and Richard Wightwick, B D	
Worcester	1714	Sir Thomas Cooke, Bart.	On site of Gloucester Hall.
Hertford . .	1874	Thomas Baring	On the site of Magdalen Hall.

teachers. This defect was overcome in different parts of Europe by different means — in Italy chiefly by state subvention; in Spain and to some extent in Germany by the annexation of ecclesiastical revenues; at Paris and Oxford, so far as it was overcome at all, by the aid of the Colleges. Originally the Regent-Masters derived their support entirely from the scanty fees of the students. The system could hardly have lasted as long as it did but for the fact that many of the Masters held Cathedral prebends or parochial benefices. But this applied chiefly to the superior Faculties, the Doctors and Bachelors of which were frequently dignified and well-beneficed ecclesiastics. In the Faculty of Arts the Masters were usually quite young men; the new Master was required to stay up and lecture for a year, and could lecture as long as he pleased afterwards. Indirectly the Colleges contributed to secure competent teachers by enabling men to take the Master's degree who could not otherwise have afforded to do so, and probably enabled many to go on lecturing for more than their "necessary regency" while beginning their studies in the higher Faculties. But, at best, formal public lectures and disputations supplied very inadequate instruction for the younger students of Arts — many of them mere boys of twelve or fourteen. In the Colleges a certain amount of less formal assistance was given to the younger members of the foundation by the older ones. At New College the younger members were assigned to regular Tutors during the earlier portion of their course. Moreover, some College Statutes provided that other members of the University might be received as paying boarders (*Commensales* or *Commoners*). When these were undergraduates, they shared in the instruction given to the younger foundationers. At Paris this system prevailed on a very large scale as early as the fourteenth century: at Oxford we hear comparatively little of it till after the Reformation; but the system of domestic instruction was no doubt more or less imitated in the Hall communities of upendowed students. And the instruction provided within the walls of Colleges and Halls was likely to be both more efficient and better adapted to the wants of young students than the formal lectures given by a young, fluctuating, and casually chosen body of Regents in the public schools. For these reasons the College teaching became more and more important and the teaching of the public schools more and more perfunctory. A University Statute of 1408 allows most of the lectures required for the degree of B.A. to be heard in College or Hall with a "recitation duly following" (*Mun. Acad.*, p. 241). This tendency was stimulated by the change which came over our University studies at the time of the Renaissance. It was in the Colleges that that increased attention

Instruction. — Originally, as we have seen, only an insignificant fraction of the University lived within College walls. But gradually a great change came over the relations of the Colleges to the University. The fundamental defect of the earlier medieval Universities was the absence of any adequate provision for the

to the teaching of Latin Grammar and composition which was the earliest phase of the Renaissance movement began to show itself; and it was in the Colleges that Greek was first taught. The promotion of these new studies was one of the declared objects of the characteristically Renaissance College of Corpus Christi, where a public "Reader or Professor of the arts of Humanity" (i.e. of Latin) whose special function it was to be to "extirpate and eject barbarity from our hive," and another of Greek (for the benefit apparently of the whole University and not merely of the College), formed a part of the Founder's scheme. The lectures in the public schools adhered to the old routine: they were scholastic lectures on the Latin Aristotle, attendance at which was more and more completely dispensed with by the University. In 1449 all the Regents are allowed to lecture out of the official University Schools in School Street (north of St. Mary's Church). In 1508 the Regents supplicate "not to be compelled to deliver their ordinary lectures for the greater part of an hour because none listen to their lectures" (*Causa est quod nulli audiunt eos legentes*, University Register; Rashdall, Vol. II, pp. 516-517). It is clear that by this time the lectures in School Street have become a farce, and all the effective instruction of the University has passed to the Colleges. Endowed professorships of divinity, civil law, medicine, Hebrew, and Greek were founded by Henry VIII in 1546, and a small number of other professorships by private benefactors in the following century. But these still left most of the instruction of the ordinary undergraduate in the hands of the College Tutors and the Principals of Halls. And of the Halls only a few survived the medieval period. Of these, all but St. Edmund Hall were merged in some adjoining College by the last University Commission.

Studies. — We must now turn from questions of organization and constitution to the studies which the organization was intended to facilitate. Law was a prominent study in almost all the medieval Universities. At Oxford, as elsewhere, a large proportion of the older, and particularly of the richer and better-born students, entered upon that faculty — usually, perhaps, after a certain amount of study in arts, not always ending in graduation. But Law was necessarily less prominent in England than elsewhere, because in England, and in England alone, a system of Law of non-Roman origin attained, early in the Middle Ages, a sufficiently scientific form to have developed a legal education of its own. Elsewhere, even when the Law was of Teutonic or non-Roman origin, its practice fell into the hands of practitioners who had studied Roman Law in the Universities, and everywhere the law of the tribunals became more or less Romanized in consequence. In Eng-

land the early growth of the Inns of Court prevented the Universities becoming in any direct and habitual manner places of education for the English bar. The Inns of Court (*q.v.*) in London were virtually a University of English Law. In the medieval Oxford the Civil Law was studied merely as a preparation for, or in conjunction with, the Canon Law; only the Advocate in the ecclesiastical Courts with a small number of practitioners in the Court of Admiralty and perhaps in the Chancery got their professional education in the Universities. After the medieval period, the study of Canon Law ceased, and any serious study of the Civil Law rapidly dwindled, though the practitioners in the ecclesiastical Courts continued perfunctorily to take the degree of Doctor as a condition of their admission to the "College of the Advocates," commonly known as "Doctors' Commons," in London.

The study of medicine was also relatively unimportant, even in the Middle Ages, though Oxford could boast a few physicians of European fame such as John of Gaddesden, author of the *Rosa Medicinae*. In post-medieval times the serious study of Medicine was connected with the Hospital Schools of London and other large towns, though the higher class of physicians still took medical degrees in the Universities. This absence of professional study left a permanent mark upon the traditions and the spirit of Oxford. Down to quite recent times it was, and as regards the majority of its students it still is, the distinguishing note of the English Universities that the bulk of their students were engaged in "liberal" studies which had no relation to their future professional occupations. Continental visitors are amazed to find future barristers engaged, up to the age of twenty-three or thereabouts, in the study of philology and philosophy, of history or natural science, and future clergymen postponing the study of theology till they have left the University.

In the Middle Ages the fame of Oxford depended mainly upon its reputation as a studium of theology and arts — that is to say, chiefly of the scholastic philosophy. The subject matter of these studies was much the same as at Paris. (See PARIS, UNIVERSITY OF.) Details varied, but here, as everywhere, the theological textbooks were the Bible and the *Sentences* of Peter the Lombard; while Aristotle — with Porphyry's *Isagoge* and some works of Boethius — formed the principal basis of the Arts course. It is noticeable, however, that in the earlier Middle Ages, physical science was treated more seriously than at Paris. The first recorded Chancellor or "Rector of the Schools," Robert Grosseteste (*q.v.*), known to the Middle Ages as *Lincolniensis*, was famous for his scientific writings. Peckham (known also as John of Pisa) wrote a famous book called *Perspectiva Communis*.

It was not a mere accident that Oxford produced that illustrious "anticipator" of scientific ideas and critic of scholastic methods, Roger Bacon. He tells us that *Perspective* was taught here when it was unknown at Paris. In his time (as we gather from his works) and throughout the Middle Ages there was rather more recognition of mathematics than at Paris. Six books of Euclid were "taken up for the Schools" (*Mun. Acad.*, p. 415). For an account of the methods of lectures and disputations, of qualifying for and taking the various degrees, the reader may be referred to the article on Universities, but it is worthy of notice that examination was rather less prominent here than at Paris. The still surviving preliminary examination, known as *Responsions* (the candidate was said *respondere questionibus magistrorum scholarum*), can be traced from the thirteenth century, but there was no examination in the strict sense for the license or the Mastership in Arts, and it is doubtful whether there was one for the Bachelorship of Arts. To obtain the master's degree nine Masters of Arts had to "depone" to his fitness "of knowledge" (*de scientia*) and nine others "to the best of their belief" (*de credulitate*). They had to judge of the candidate's efficiency, it would appear, merely from his performances in the various disputations and his general reputation. It is a curious illustration of the continuity which characterizes Oxford history that nine Masters of Arts must still be present in the "ancient house of Congregation," for the conferment of an ordinary degree.

Fame and Numbers — We have seen that very early in the thirteenth century Oxford already boasted of 3000 students, according to the medieval estimate, *i.e.* probably in reality less than 1500. It was by this time the most famous university in Northern Europe, next to Paris. Already in 1257 Matthew Paris calls Oxford "the second school of the Church" (*Chron. Maj.*, V. 618). It could boast famous teachers in Robert Grosseteste, Roger Bacon, the canonized Edmund Rich, and John Peckham, Archbishops of Canterbury. But it was not till the end of the thirteenth century that Oxford produced a great schoolman who could rival the reputation of Thomas Aquinas and the other great Parisians. Paris had been the scene of the great scholastic movement which had substituted an Aristotelian for a Platonic-Augustinian Philosophy as the basis of the Church's scientific Theology. The task of refuting the unorthodox "Averroistic" interpretation of Aristotle, of Christianizing Aristotle and Aristotelianizing Christianity, had been the work of the great Dominican Doctors at Paris. The attempt, while teaching and expounding the newly recovered Aristotelian works, to remain faithful to the older Platonic tradition, was begun by the Franciscan Doctors at Paris, but attained its fullest development in the

rival and more conservative University of Oxford, where the Franciscan order possessed more influence than their rivals, the Dominicans. The Franciscan convent at Oxford — whose memory lingers in "Paradise Square" and "Friar's Street" — was the true home of that new epoch in the development of the scholastic Philosophy which culminated in "the subtle Doctor," Duns Scotus (*q.v.*), who introduced the thoroughgoing Realism of the later Middle Ages. But this return to Realism provoked a nominalistic reaction; the germs of both movements may be detected in the works of the earlier Franciscans, especially Roger Bacon (*q.v.*). William of Occam, the "invincible" Doctor, the founder of the later nominalistic school, was likewise an Oxford Franciscan. During the fourteenth century Oxford — though a smaller University and less frequented by foreign students — was the home of a far more vigorous and original scholasticism than Paris or any other continental University. It was during this century that the numbers rose to their highest. The medieval estimates of 30,000 or even 60,000 students are quite fabulous; but there may have been some 3000.

Among the schoolmen of this period may be mentioned the Franciscan, Richard of Middleton; John Dumbleton of Merton; Walter Burley, the "plain and perspicuous Doctor" of Merton; Robert Holkot; the Carmelite, John Baconthorpe, "the resolute Doctor"; the "profound Doctor," Thomas Bradwardine Balliol, afterwards Archbishop of Canterbury; and John Wycliffe, for a time Master of Balliol, the "Evangelist Doctor." The list closes with Wycliffe, who was for the most of his life a resident Oxford Doctor, and was a realistic schoolman of European reputation before he developed the original views which gradually broadened out into undeniable heresy. Wycliffism was essentially an "Oxford" movement, originating there and for a time dominating the University and sending forth a constant succession of "poor priests" to preach a new evangelical and anti-monastic Christianity throughout the country. It was not till about the year 1411 that an effective attempt was made to purge the University of "Lollardy." The attempt succeeded, and with Lollardy all serious scholastic thinking was suppressed. Wycliffe ends the list of famous Oxford schoolmen. It was in part the reputation for heresy which Oxford had acquired which induced pious founders to establish new Colleges at Cambridge, and pious parents to send their sons to that University. At all events it is from about the period of Wycliffe that Cambridge began to take a place of some equality with Oxford.

Renaissance and Reformation Period. — In Oxford more even than elsewhere the fifteenth century was a period of intellectual decline. Scholasticism was getting played out, and

vigorous minds began to look in other directions for intellectual sustenance. The first sign that can be detected of a Renaissance consists simply in an increased attention to that preliminary training in "grammar" which always formed the basis of University studies, but which had been neglected since the Aristotelian furor of the early thirteenth century had thrown all other studies into the shade. The effects of Wykeham's provision that students of his New College should stay in the Grammar School at Winchester till they were sixteen — a late age for the medieval freshman — bore fruit. The Latinity of Thomas Chaulder, Warden of New College from 1454, has a classical ring about it, and to him is due the first introduction of Greek into Oxford. It was within the walls of New College that the Italian scholar, Thomas Vitelli, taught Greek from about 1475 till 1488 or 1489; and from him no doubt the first of English humanists, William Grocyn (*q.v.*), Fellow in 1467, received his initiation into Greek, which he afterwards taught at Magdalen, and after traveling in Italy, at Exeter in 1498, where he numbered More and Erasmus among his hearers. Erasmus resided at Oxford as the guest of Prior Charnock in St. Mary's College (the College of the Augustinian Canons, of which some remains are still to be seen in New Inn Hall Street) for some months in 1499, and from 1496 till 1504 John Colet was also teaching the Greek Testament in Oxford. Erasmus is full of compliments for the Oxford band of scholars. The brilliant promise of these years was hardly fulfilled. Theological controversies, revived by the Reformation movement, were too strong for much of the genuine Renaissance spirit to flourish in Oxford as yet. But still the knowledge of Greek and of classical Latinity went on growing. Aristotle began to be studied in the original Greek, and the theologians read the Schoolmen less and the Fathers more. The theological controversies were at least fought with new weapons — the weapons of classical scholarship and patristic learning, as well as the old scholastic dialectic. Henry VIII and the ecclesiastics favored by him sympathized with the positive side of the new Learning, and still more with its ferocity against the old. In 1535 a Royal Commission was appointed to visit the University. Here is a report of their proceedings at one of the Colleges: "In New College we have established a lecturer in Greek and another in Latin with an honest salary and stipend. . . . We have set Dunsce [i.e. Duns Scotus] in Bocardo [the cant name for the town prison over the Northern Gate], and have utterly banished him Oxford forever, with all his blynd glosses, and is now made a common servant to every man, fast nayled up in all common houses of easement — *id quod oculis meis vidi*." (Wood, *Annals of Oxford*, Vol. II, p. 62.)

The accession of Edward VI brought with it a new Commission. Fellows suspected of Romanizing tendencies were removed; many of them fled to the continent without waiting to be deprived. Avowed Protestants were put into their places. Peter Martyr was brought to England and made Regius Professor of Divinity. The effect of the Edwardian Reformation was almost to empty the University of unendowed students. The majority were of course anti-Protestant; much of the monastic property was gone; Oxford lost the monks and friars who had formerly taken courses in the University, and the exhibitions which wealthy Abbots had supplied to enable promising lads to study. No one knew what was to become of the Church's remaining property. The Church was no longer a safe career. The numbers of the University were reduced to about a thousand or less (Wood, *Annals*, Vol. I, p. 113). As the University filled up again in the time of Queen Mary and Elizabeth, the majority of the unendowed students became boarders in the Colleges — styled according to their rank and the payments they made "noblemen," "gentlemen-commoners," "commoners," or (if they lived after the manner of servitors) "battlers." A few Halls alone remained, in which the Principal lived entirely on the payments of the commoners, and education was organized very much on the model of the Colleges. The public schools were resorted to only for the disputations required for the various degrees or for the lectures of the few endowed professors. Each of the changes of religion brought with it a Commission, and a purgation of the Colleges by the removal of adherents of the beaten party. But few things enable one to realize better how very gradual was the real establishment of Protestantism in the University as in the country generally. It was not till after Elizabeth's excommunication and deposition by the Pope in 1570 that really effective methods were taken to get rid of Romanizers from the foundations. As we near the end of Elizabeth's reign, Puritanism — i.e. Calvinism in doctrine — became more and more dominant in the Universities, though less so at Oxford than at Cambridge. The most marked reaction against it came likewise from Oxford. Reason and conscience revolted against some elements of the Calvinistic creed; learning discovered that the discipline and ritual of the ancient Church, if it was not that of medieval Rome, was equally far removed from the Genevan model. The leader of the revolt at Oxford was William Laud (*q.v.*), a Fellow from 1593, and from 1611 to 1621 President, of St. John's College, which still treasures in its Library the copes which he provided for use in the College Chapel. The High-Church reaction in politics and religion had its center in Oxford. But nothing can testify more eloquently to the hold which

Calvinism in doctrine had obtained over Oxford, even among those who were strong supporters of Episcopacy and the Prayer-book as against the Presbyterian worship and discipline than the fact that even Laud himself in the height of his power (1635), while remonstrating with the Bishop of Winchester as to the condition of New College, did not venture to deny that "Calvin's *Institutions* may profitably be read" by students in the University, though he ventured to suggest that it was premature to make it the chief subject of study and examination for young scholars in their first two years after coming up.

Laudian Statutes. — In 1630 Archbishop Laud was elected Chancellor of the University. Towards the end of the fifteenth century it became common for the University to elect as a Chancellor an Archbishop or Bishop — later on sometimes a lay noble — who was of course usually, if not always, an absentee, leaving the practical duties of the office to be discharged by a Vice Chancellor, usually the Head of a College. But the Chancellors, though nonresident, were by no means disposed to treat their office as a sinecure; their *raison d'être*, in fact, was to protect the interests of the University at Court, and at the same time to govern it in accordance with the political and religious policy of the government for the time being. Laud might be trusted to avail himself to the full of the opportunities which he enjoyed as Archbishop, as Chancellor and as Visitor of two important Colleges. Nothing was too minute for this ecclesiastical disciplinarian, whose insistence on the "four surplices at All-hallowtide" in every parish cost the Church of England so dear. As Visitor of All Souls' he required the Warden to insist that the Fellows "use not long undecent hair, nor wear large fulling bands, nor boots under their gowns, nor any other like unstatutable novelty." Preachers who attacked Pelagianism or Arminianism or ceremonialism, were imprisoned or banished the University, or at least required to read recantations on bended knees in the Convocation house. At the same time Laud was a real patron of learning, bestowed a valuable collection of Oriental and other Mss. upon the great Library founded by Sir Thomas Bodley in 1602, and endowed a professorship of Arabic. But the greatest memorial of his Chancellorship is the compilation of a new code of statutes, — the first systematic codification of the University's laws and customs which had ever been undertaken.

Since the close of the medieval period the old order of the University had been more and more falling to pieces. The statutes had largely become obsolete; it was hardly known which of them had been and which had not been legally repealed; the old machinery of lectures in the schools, examinations, disputations, and other exercises for degrees, had

little relation to the real studies of the place, which for the most part went on in the Colleges over which the University had no control. The old forms were sometimes kept up, sometimes dropped. On paper, the University was still the University of the Middle Ages, teaching scholasticism in its public schools; in practice it had become an aggregate of almost autonomous Colleges, which taught no doubt with some of the old-time knowledge the learning of the Renaissance and the Reformation. It is unnecessary to trace the various attempts at reform of the University constitution which took place in the course of the sixteenth century and the first half of the seventeenth. Laud's more vigorous exertions led to the enactment in 1636, — by the combined authority of the University, the Chancellor (to whom the University had conceded special powers in the matter), and the Crown, — of the code under which (with very few alterations or additions) the University nominally lived down to the middle of the nineteenth century. Although the University still remained without any effective control over the internal affairs of those societies, the Laudian Statutes recognized the fact that the University had largely become a federation of Colleges. The "Heads of Houses" (i.e. of Colleges and Halls), with the addition of the two Proctors, were now constituted into a probouleutic Council, without whose consent no permanent statute or temporary "decree" could be brought before the "Convocation" of Doctors and Masters of Arts; and the old "Black Congregation" was abolished. A small body of Heads could be more easily managed by the authorities than the democracy of young Fellows. This body held weekly meetings and acted as the supreme executive of the University; it was commonly known as the Hebdomadal Board. The Vice Chancellor was always to be the Head of a College, nominated by the Chancellor for a year at a time. In practice, he was frequently reappointed, — in modern times usually for four successive years. The Proctors were now nominated by the Colleges in turn, and in various ways the Colleges and their officers received a recognition from the University authorities, though the attempt to secure control of them by the University, e.g. by giving the Vice Chancellor power to remove Tutors, did not practically amount to much. The Statutes did not merely stereotype the organization of the University; they attempted to regulate its studies. The medieval disputations were retained, but a regular examination for the degrees of B.A. and M.A. was added. And the attempt was made to galvanize into life the lectures in the public schools given by the Regents elected every two years — one in each of the "three Philosophies and seven Arts" in which there was no endowed Professor. Undergraduates and Bachelors of Arts were required to attend, for different parts of their

Oxford.

course, the lectures of the Professors or Praelectors of logic, of moral philosophy, of geometry, of astronomy, of natural philosophy, of metaphysics, of history (a recent foundation by the antiquary Camden), of Greek and of Hebrew. This magnificent program might seem to leave little time for the lectures or private instruction in the Colleges. And yet it is certain that the most serious work of most undergraduates—even in the seventeenth, and still more in the eighteenth century—was the work which he did with his tutor in College. Even in Wood's time—i.e. a generation or two after the Laudian reforms,—the lectures of the Regents in the schools had acquired the name of "Wall-lectures"—which in a farcical form continued to be delivered after the beginning of the nineteenth century (Cox, *Recollections of Oxford*, p. 37 sq.).

The Great Rebellion; Restoration.—The Civil War produced a violent solution of continuity in Oxford history. For some time Oxford was at once a Court and a camp; the King was quartered at Christ Church; Ministers of state and courtiers were thrust into the rooms which should have been occupied by Fellows and Scholars; hundreds of scholars took arms. Even the Puritan régime, which followed, hardly got rid of all the demoralizing effects of this episode. After the triumph of the Parliament a Commission was appointed to visit the University and Colleges, and those who would not acknowledge the authority of the Visitors were "outed" (1647-1648). Men of sounder political and religious views were thrust into their places. Assuming the necessity of such a purgation, the revolution was carried out with moderation. Some of the men put into the places of deprived Heads and Professors were among the most distinguished men of their time, such as the mathematicians Wilkins, Warden of Wadham, and Wallis, Professor of Geometry, and Pococke, who became Professor of Hebrew. With the Restoration a great decline in learning set in. In part, this was no doubt due to tendencies of the time which had nothing to do with politics. The first half of the seventeenth century was the learned age of Europe. The second half was an age of scientific discovery, of popular religious and philosophical controversy, of belles lettres. These influences affected Oxford negatively by weakening zeal for the old studies, if they did not lead to much educational reform. In particular, there was a conspicuous decline in the study of Greek; and the exaction of Hebrew imposed by the Laudian Statutes on B.A. students, if it ever took effect, certainly disappeared. Anthony Wood looks back with amazement on the fact that before the Great Rebellion there were men who used to "discourse in the public schools very eloquently in the Greek tongue" (Life of Henry Stubbe in *Athenæ Oxon.*). The growth

of coffee-houses from 1650 onwards is at once an indication and a cause of the changed spirit of the place. "Why doth solid and serious learning decline and few or more follow it now in Universities?" asks the same writer in 1678 (*Life and Times*, ed. A. Clark, Vol. II, p. 429). "Answer—because of Coffee-houses where they spend all their time." Time spent in the coffee-houses was not all wasted. Here men read the *Spectator* and the newspapers, and discussed the latest book in the deistic controversy. At about the same time the Colleges began to make themselves comfortable. Fellows now lived in separate rooms, and "common-rooms" were built in which Fellows talked and boozed away most of the time after dinner, instead of retiring to their rooms and resuming their studies, as they were required to do by the College statutes. It must not be supposed that there was no learning or study in the Oxford of the Restoration and the eighteenth century. At the worst times there were always isolated Fellows who used the leisure secured to them by the College endowments for the purposes for which these were given, and there could always be discovered isolated Tutors who took their duties seriously. A little before the Revolution John Locke (q.v.) was a resident student and Lecturer of Christ Church. Among the professors of the eighteenth century were distinguished men, such as Halley the astronomer, Blackstone the lawyer, and Lowth, afterwards Bishop of London, whose lectures on the poetry of the Hebrews were long a classic. But the professional lectures were for the most part on subjects unconnected with the compulsory studies of the ordinary undergraduate, or with any organized curriculum. Of the tutors, too many resembled the unfortunate man intrusted for a brief period with the education of the youthful Gibbon, who has handed him down in his *Autobiography* to the contempt of posterity, as one who "well remembered that he had a salary to receive but forgot that he had a duty to perform," and the equally unfortunate "monks of Magdalen" whose "conversation stagnated in a round of College business, Tory politics, personal anecdotes, and private scandal," and whose "dull but deep potations excused the brisk intemperance of youth."

The eighteenth century was—till towards its close—to some extent a period of academic torpor or decadence all over Europe. (See EIGHTEENTH CENTURY, etc.) But it is probable that no University ever sank quite so low or began its revival so late as the University of Oxford. That revival corresponds pretty exactly with the beginning of the nineteenth century. I propose to enumerate a few of the facts which may be regarded in part as symptoms, in part as causes, of this extraordinary decay. It will be observed that most

of them spring from defects in the Constitution of the University which date back in many cases to the early Middle Ages, and which successive Parliaments and Governments had never made the slightest attempt to correct or reform.

(1) The fundamental defect in the constitution of Universities of the Parisian type was the absence of proper salaries for the teaching body. Everywhere the defect had somehow to be remedied, nowhere was it remedied so badly and so imperfectly as in the English Universities. The few professorial endowments supplied by Henry VIII or private benefactors became, with the decline in the value of money, increasingly inadequate. It became difficult to insist even on continuous residence; in some cases the lectures ceased to be given. It appears that about the year 1800 fifteen out of twenty professors offered lectures of some kind, but in some cases they had to be abandoned for want of an audience (*Vindication of Magdalen College*, 1800). The Regius Professors continued to be paid their £40 per annum till the middle of the nineteenth century. The rest of the teaching was left to the Colleges.

(2) College Tutors were chosen from Fellows of each College. But fellowships were never intended to remunerate teachers. The legal restriction in many cases to particular dioceses or counties, or a non-legal tradition of electing solely from the College, narrowed the field from which Fellows could be chosen. Consequently Tutors could not always be efficient, and the medieval restriction on marriage remained; even when there were no clerical restrictions on Fellowships, it was the tradition that Tutors should be in holy orders. The abler the man, the more certain he was after a few years of residence to go off to be Tutor to a nobleman's son or to take a benefice in the gift of the College. Teaching was chiefly in the hands of young men who did not intend to make a profession of teaching. Though, as late as the beginning of the eighteenth century, we sometimes find a systematic division of subjects and classes among College Praelectors, the tendency was more and more to leave the teaching of the undergraduate mainly in the hands of his own Tutor. Nobody could be efficient in all subjects; the result was the restriction of teaching to a few subjects—those which the average tutor knew best. By the middle of the eighteenth century little was taught but the classics and a little Logic. The average standard was low. The complaint that he had been fined twopence for not attending a lecture which was not worth a penny, was Samuel Johnson's testimony to his own Tutor's competency; and his experience was not exceptional. In reading the biographies and other records of the period, one is often astonished at the amount of learning and serious study which was to be

found in Oxford even at its worst, but it it nearly always the studies which a select few of the Fellows carried on without reference to teaching, and which a select few of the undergraduates carried on in their own rooms without any regard to the requirements of lectures or examinations.

(3) If the Tutors were inefficient, still less were the bulk of the Fellows not engaged in tuition really fit for the higher studies which they were supposed to be pursuing; and there was little inducement to become so. The part of the Laudian Statutes which related to the studies in the higher faculties, and even to those studying for B.A., soon became obsolete; and eventually a few months' residence was all that was required between B.A. and M.A. For the majority, the real education of unendowed students ended with the B.A. degree. Even in the case of Fellows, excuses for non-residence came to be more and more freely accepted. By the end of the eighteenth century it had come to be understood that, at least after taking his M.A. degree, a Fellow was allowed to be resident or non-resident as he pleased, and nothing whatever interfered with the idleness of those who chose to stay in Oxford. At some colleges—especially All Souls and New College—the practice of "corrupt resignation,"—i.e. a Fellow being allowed to take a bribe from a man who wanted to succeed him—added to the abuse by closing the fellowships to poor men.

(4) The area from which students would be drawn was narrowed by the close connection of the University with the established Church. The requirement of subscription to the thirty-nine Articles by every undergraduate at the age of sixteen, was not removed when religious toleration was established in the country at large. The fact that there was more religious liberty in England than in most continental countries, and consequently more dissenters from the State Church, only increased the number of the excluded. Moreover, as the Universities practically ceased to educate for the professions of law and medicine, the class which required a university education was smaller than elsewhere. The Church (in which the profession of the higher schoolmaster was virtually included) was the only career for which the University made any attempt to educate; and the medieval tradition remained by which a course in Arts was practically the only education received by the bulk of the clergy, though a few Divinity lectures were usually given to all undergraduates in college. The expensiveness of the colleges, except for the foundationers and the despised class of servitors, and their growing reputation for idleness and inefficiency aggravated the evil. They fell into disfavor with the more strenuous and progressive classes. The number of undergraduates at Oxford at the end of the eighteenth century was

much smaller than it had been at the beginning of it. By that time the benefits of a University education were practically confined to the future clergy, the sons of the landed gentry, and a very small section of the professional class which, with or without assistance from the foundations, could afford such a luxury before beginning their training for the bar (in England a very small profession), or medicine, or the like.

(5) The examinations prescribed by the Laudian Statutes had become a pure farce. The candidate was allowed to choose his own examiners; he could thus select a couple of young M.A.'s whom he entertained at a feast the night before. The examiners were expected to ask, and did ask, traditional questions, the answers to which the undergraduates had learned by heart from "schemes" or little books provided for the purpose a few days before the examination. The disputations and other conditions required for the degrees — higher and lower — had equally degenerated into the purest formalities when they were not "dispensed" by Congregation.

Revival in the Nineteenth Century — To those who look back upon the condition of the University at the end of the eighteenth century the wonder is that the dry bones should ever have lived again. It is vain to speculate on the causes of the revival which first showed itself in the first years of the century: some may suggest the French Revolution, others the indirect effects of the religious revival which dates back to Wesley; or it may be that the very extremity of the disease awakened in the minds of a few able men a sense that something must be done to cure it. Certain it is that the eighteenth century was a period of progressive decay, the nineteenth century one of reform. The era of reform must be divided into two portions. During the first half of the century the reform came wholly from within; there was a revival of learning, of education, and of religion, with little change of machinery; what changes did take place were initiated by the University itself. During the second half of the century the reforms were largely imposed upon the University from without, *i.e.* by Parliament, at the instigation and with the assistance of a reforming party within, but in ways to which the University as a whole would never have consented.

Reform began in 1800 with the "new Examination Statute" which substituted a real Examination in place of the old pretence of one. Competent examiners were appointed by the University; a certain degree of proficiency was required for what was now called a "pass degree," while a list was published of those who had taken "honors," divided into two or (from 1808) three classes; a fourth class was added in 1831. There were two lists of honors — one of those who had dis-

tinguished themselves in *litteris humanioribus* (*i.e.* classics, ancient history, ancient and modern philosophy) and one in *Disciplinis Mathematicis et Physicis*. It is not too much to say that the improvement which soon began to take place in the industry of undergraduates, in the efficiency of the teaching and in the tone of life among the seniors has been chiefly due, directly or indirectly, to the stimulus supplied by these examinations, especially by the competition for honors between Colleges and individuals. High honors soon became so much esteemed by the general public that a First-class — still more, what was then called a "double first" (*i.e.* in classics and mathematics) — was supposed to mark a man out for distinction in Church or State, and the fact that he had taken one was still remembered to his credit when he had become a Prime Minister or an Archbishop. The number of "honour men" was at first small; they have now increased till they are more numerous than the "pass men."

Owing perhaps in part to the new examinations, a few Colleges began to attend, as they had never done before, to merit in the election to fellowships and scholarships. Balliol laid the foundation of its future distinction by opening its scholarships to competition among all comers. Oriel did the same with its fellowships; and an Oriel fellowship became the blue ribbon of the University. The growth of the "first Oriel school" — a group of men of mildly rationalistic or liberal tendencies — is the first sign of reviving intellectual life. Bishop Copleston (Provost 1814-1828), Archbishop Whately, and Bishop Hampden are its best remembered representatives. They were soon succeeded by the "second Oriel school," from which sprang the religious movement in the Church of England known as the "Tractarian" or "Oxford" movement, which began about the year 1833. (See KEBLE, JOHN; NEWMAN, JOHN HENRY.) Reactionary as were its intellectual tendencies, the movement did lead to a revival of serious theological study; and, if it absorbed the tutors in theological controversy too much to make for educational efficiency, it at least produced a higher standard of personal behavior and tutorial duty; while its increasingly Roman tendencies stimulated a liberal reaction which was in sympathy with the growing demand for University reform outside. When Newman joined the Roman Catholic Church in 1845, this liberal tendency was powerfully reinforced. "If any Oxford man had gone to sleep in 1840 and had woke up again in 1850," says Mark Pattison (*Memoirs*, p. 244), "he would have found himself in a totally new world. In 1840 we were in Old Tory Oxford, not somnolent because it was fiercely debating, as in the days of Henry IV, its eternal Church question. . . . In 1850 all this was suddenly changed as if by the wand

of a magician. . . . Very free opinions on all subjects were rife. . . . A restless fever of change had spread through the colleges — the wonder-working phrase 'University reform' had been uttered, and that in the House of Commons. The sounds seemed to breathe new life into us. We against reform! Why, it was the very thing we had been longing for; we were ready to reform a great deal — everything — only shew us how to set about it and give us the necessary powers."

Reform Period. — *University Reform Act, 1854.* — The exertions of the Reformers inside and outside the University at last led to an Act of Parliament which appointed a body of Commissioners with power to inquire and make recommendations for the reform of the University. They presented in 1852 a report which led to the University Reform Act of 1854. The changes introduced by this measure, or by the Executive Commission appointed under the act, may be thus summarized: (1) For the old "Hebdomadal Board" of Heads was substituted a "Hebdomadal Council," consisting of the Chancellor (nominally), the Vice Chancellor, the ex-Vice Chancellor, the two Proctors, and eighteen members elected by a new body called the Congregation — of whom six must be Heads of Houses, six Professors, six members of Convocation. (2) The new "Congregation" consisted of all resident Doctors and Masters; a new Statute has to be passed by this body before coming before Convocation, and the power of amendment is vested in this body alone. By (it is believed) a mere oversight the old Congregation of Regents — now known as the "ancient House of Congregation" — was not abolished, and remains the authority for the conferment of ordinary degrees and a few other formal purposes. (3) A certain number of new professorships were founded, and the endowments of old ones increased out of the revenues of certain Colleges. (4) In the Colleges most of the local restrictions for fellowships and scholarships were swept away, and it was provided that they should be filled by public competition. (5) The religious test was removed as regards undergraduates and bachelors, but it remained for the degrees which secured admission to the governing body of the university. It was not till 1871 that "tests" were abolished for all degrees except those in Divinity, for fellowships, and for all University and College offices except those confined to clergymen.

Internal Reforms. — Reforms from within now began to follow one another with great rapidity. In 1852 the classical course was broken up into two sections: (1) An examination known as the First Public Examination, popularly known as "Moderations" because conducted by "Moderators," which was almost purely classical, taken in the course of the second year, and (2) the final examination,

to which the name of *Litteræ Humanioribus* was now confined, which was less classical and admitted a larger element of philosophy and ancient history than the old, undivided School. A similar division was effected between purely mathematical "Moderations" and a School of Mathematics and Physics. Other honor examinations or "Schools" (implying fresh courses of study) now began to be founded; their names up to the present are as follows, with dates of the first examination in each case: natural science (1853); law and modern history (1853, broken up into two separate schools in 1873); theology (1870); Indian languages (1887), Semitic languages (1892), now united as a school of Oriental languages; English literature (1898); modern languages (1905). Numerous changes have taken place in the Pass School, in which a large number of "options" is now allowed. The first stone of the University Museum was laid in 1855, and has been followed by a succession of buildings to meet the requirements of students in natural science and medicine.

University Commission, 1881 — The next great legal change in the organization of the University was effected by an Act of Parliament passed in 1877, and by the Statutes of a Commission appointed under the Act, which were made in 1881. The changes which now took place were of a more sweeping kind than in 1854: (1) The Latin statutes (mostly medieval) of the Colleges were repealed; concise and businesslike English statutes were substituted for them, while an easy method of subsequent amendment (by Order in Council on the petition of a College) was provided. (2) The life tenure of fellowships — a feature almost peculiar to Oxford and Cambridge among medieval Universities, and the source of their worst abuses — was abolished. Elections were now to be for seven years in the case of non-resident or "Prize" fellowships, while Fellows engaged in educational work were to hold their fellowships — subject to periodical reelection — as long as they discharged the duties. Power was also given to elect to fellowships persons engaged in "research." (3) The requirement of celibacy (which had been to some extent modified for particular Colleges by special enactments of the late Commission) was abolished, subject to provision securing the presence of a certain number of unmarried Fellows to reside in College. (4) All clerical restrictions upon the election to headships and fellowships (with the exception of Christ Church, whose Head was also Dean of the diocesan Cathedral, and one other College) were now removed, except in the case of one fellow (occasionally two or three) who were usually left for the conduct of the College services and the provision of theological instruction. (5) Further professorships were endowed, and the endowments of existing professorships increased by the

annexation of a fellowship in one of the Colleges to the respective chairs, and by the imposition of further payments upon the College revenues. (6) Other payments for University purposes were imposed upon the Colleges (when their revenues were sufficient) in proportion to their wealth. (7) The value of fellowships — hitherto very variable — was reduced to a uniform £200 or (in some cases) for fellows engaged in teaching £300 per annum.

Other Reforms and Institutions. — The effect of these changes was to transform the University from a mediæval and largely clerical institution, or group of institutions, into a modern University, and the body of College Tutors into an independent and permanent profession. But the changes which were introduced by private and extra-legal action on the part of the Colleges before and after the Commission of 1881 were quite as important as any which appear upon the face of the Statute-book. Private arrangements between a small number of Colleges for combined or intercollegiate lectures began about the year 1870, and were gradually extended until virtually all honor-lectures throughout the Colleges were open to the whole University. The College Tutors were thus relieved from the burden of too many lectures on too many subjects, which had been one main cause of tutorial inefficiency. The College Tutors were in fact transformed into a body of supplementary University teachers. The arrangement eventually obtained a semi-official recognition from the University, and a recent Statute (1911) has now definitely organized the whole body of College Tutors and Lecturers into "Faculties," who elect representatives to sit and vote with the Professors as members of Faculty Boards. As a consequence of this change and of the general widening of intellectual interests, the old style of lecture, which was mainly a construing lesson, for the most part disappeared, and what used to be called the "professorial" manner of lecturing took its place. At the same time, by a spontaneous but rapid evolution, a system developed under which the College Tutor imparted instruction chiefly by hearing and discussing essays with single pupils, or two or three pupils together. The practice appears to have become common somewhere in the second quarter of the nineteenth century — and was soon expected of every Tutor; it now constitutes the most characteristic feature of Oxford education.

A few other recent changes may briefly be mentioned: (1) In 1868 it was made possible for students to keep the statutable residence for degrees, and to obtain at small expense the benefits of University study without being members of a College or Hall; there are now some 250 "non-collegiate students." (2) In 1863 the University undertook, jointly with Cambridge, a system of examination for schools

(under a joint Schools Examination Board), and in 1873 a system of local examinations (senior and junior) for boys and girls, — chiefly intended for those who do not intend to proceed to the Universities, — which has had a marked effect in improving the efficiency of the secondary schools throughout the country. (See EXAMINATIONS.) (3) In 1879 women began to be admitted to College lectures and, by private arrangement with the examiners, to some of the examinations. The names of women first appeared in a supplementary official class list in 1893. Nearly all the examinations are now open to women, but Convocation has so far refused to admit them to the actual degree. Four Halls for the residence of women students have been provided: Somerville College (1879); Lady Margaret Hall (1879: Church of England); St Hugh's Hall (1886); St Hilda's Hall (1893). (See WOMEN, EDUCATION OF.) (4) A system of "University Extension" for providing lectures of a University character in towns throughout the country was instituted tentatively in 1878 and definitely in 1885; while in 1909 a system of "Tutorial Classes" for the more thorough instruction of workingmen students was established by the University in consultation with representatives of the trade-unions. (See UNIVERSITY EXTENSION.)

The growth of special studies which could not conveniently be made the subject of an Honors School has led to the organization of various courses which do not lead up to a degree. The institution of the Rhodes Scholarship by the South African millionaire, Cecil Rhodes, sometime Prime Minister of Cape Colony, which enables a large number of American, Colonial, and German students, often somewhat older than the bulk of English undergraduates, to study in Oxford, has tended in the same direction, and stimulated a demand for "postgraduate" education. (See RHODES SCHOLARSHIPS.) The presence of a small number of former students in the "tutorial classes" also constitutes a body for which the ordinary curriculum is unsuited. These new demands have in part been met by the institution of a number of diplomas accessible after a shorter course of study than is required for the Degrees. The following courses leading to Diplomas have so far been instituted: anthropology; archaeology; economics and political science; forestry; geography; rural economy; scientific engineering; and the theory, history, and practice of education.

Present Problems. — How far the revolution of 1881 and the changes consequent upon it have done all that is required in enabling the University to meet the educational requirements of modern England is a question about which opinions are at present divided. Inside and outside Oxford there are those who would like to reduce the Colleges to mere boarding-houses, to pool their revenues, and

completely to reorganize the University on the German model. There are, of course, conservatives who would alter nothing or be content with the smallest amount of change which would avert a new Commission. There is an intermediate school — representing perhaps the largest section of the resident teachers of the University — who would retain the “tutorial system” as the most characteristic and the most successful feature of the present organization, while they recognize the necessity of considerable changes, not so much in the way of another violent revolution from without as to give the actual working part of the University the power, which it at present lacks, of reforming itself. Without attempting a discussion of proposed remedies, it may be convenient briefly to notice the features of the present system most subject to criticism: (1) The University is governed in an extraordinary and (except at Cambridge) unparalleled manner. Through the changes in the method of taking the B.A. degree, nothing has been done to make the M.A. a reality, that degree is still accessible to the B.A.’s of a certain standing and on the payment of fees without any examination. Even “Congregation” — composed of resident M.A.’s — includes many casual residents in Oxford who may have taken no more than a pass degree, and have no official position in the University or any College, while the supreme governing body of the University still consists of all M.A.’s, resident or non-resident, who qualify by the payment of a small fee. A summons from the conservative wirepullers in Oxford can always be trusted to bring up a few hundred Masters — largely country clergymen — to defeat the schemes which have commended themselves to the majority of the teaching body. The rejection of a proposal to abolish “compulsory Greek” in Responsions for students intending to graduate in mathematics or natural science is the most recent exploit of this legislative mob. (2) Although of late years an increasing number of fellowships have been bestowed upon persons engaged in educational work or “research,” a considerable number of non-resident or “idle” Fellows remain. Whereas with the reformers of 1881 one of the chief objects was to use the fellowships as a means to starting men in professions instead of providing inducement to “hang about” Oxford, it is now widely felt that this was not the purpose for which Universities and Colleges were endowed. (3) A large portion of College revenues is devoted to granting scholarships — mostly of £80 for four years — often to the sons of more or less wealthy parents. (4) The Commissioners of 1881 — elderly men educated on the old system — had little sympathy with the modern conception of a University as an institution not only for teaching, but for the promotion of research and learned work. In the subjects

largely studied by undergraduates there are some two or three Professors for twenty or thirty College teachers engaged in the same study. These men are often so hard worked that they have insufficient leisure to do anything considerable in the way of research and learned production; the chances of succeeding to a professorship, even at fifty or sixty, are small, and there is little other encouragement to such work. Further, the College Tutors begin their work too early and without adequate preparation, — often in the very year after they have finished their own B.A. course. (5) There are complaints of the tyranny of examinations. Some would like to supplant or supplement them by the requirement of “dissertations” and the more direct training in the methods of original research which such a requirement would stimulate, while others would prefer to provide for the encouragement of such work by postgraduate study. (6) There is a want of cooperation and co-ordination between the various University authorities concerned with finance, and between them and the Colleges. (7) There are the long-standing complaints as to the expensiveness of the Colleges, and the virtual exclusion of poor men from their advantages. Among the most advanced reformers it seems to be considered that University and College revenues should chiefly be devoted to the support and education of workingmen students. The return to power of a Liberal Government, with an enormous majority at its back, in 1906 stimulated the outcry for University reform. The moderate reformers within the University were encouraged to make an effort for such “reform from within” as would avert the necessity for a Commission. The present Chancellor, Earl Curzon, seconded their efforts and published a book in which he made various suggestions. Reforms for legislation more or less on the lines proposed by him have been introduced by Council. Some of them have been rejected; others are still under discussion. The great obstacles to reform from within are the fact that some of the changes most generally demanded — such as a diminished expenditure on non-resident Fellows and scholars who can come to the University without assistance — require a unanimity among twenty independent governing bodies which has so far not been secured, while the cumbronsness, ultraconservatism, and ignorance of the ultimate governing body of the University make it improbable that any considerable proposals for reform will pass into a Statute, even when they are recommended to them by a leading conservative statesman whom they have themselves elected to the headship of the University. If this article is maintained, parliamentary intervention is sooner or later inevitable. Meanwhile reformers may console themselves with the reflection that now, as in the past, some of the advances most needed

in the studies, the teaching, and the general tone of Oxford may be — and to a large extent are being — carried out by the silent development of public opinion among that much criticized body of men, the College Tutors, who are still taking the largest share in the real work of the University.

There are now 57 professors of the University, over 50 university readers and lecturers (but some of these are also college tutors, etc.), nearly 200 college tutors and lecturers, and nearly 3000 undergraduate students in residence, and about 150 resident B.A.'s still largely engaged in study. The number of women students in Oxford (unmatriculated) is 341. H. R.

PACIFIC COLLEGE OF THE, SAN JOSÉ, CAL. — An institution of higher learning situated in College Park, halfway between the towns of San José and Santa Clara. The institution was the pioneer Protestant college of California. The first charter was granted in 1851, and the school was opened in Santa Clara, May 21, 1851. In 1871 it was removed to its present location. The college owns a tract on the Alameda, which will be used for the erection of other college buildings. Though previous to 1911 a university in name, the institution has never attempted to do more than college work. However, in the decade of the fifties it established the first medical school in the state. This school later became incorporated as the Cooper Medical School of San Francisco, which in time was acquired by the trustees of Leland Stanford Junior University. Throughout its history the college has been under the patronage of the Methodist Episcopal Church, but is in no sense sectarian. As early as 1852 the college voted to admit women to its courses. As integral parts of the institution until June, 1911, were the preparatory and music and art departments. On the date named these departments were separately organized under the same president and trustees, and are now known as College Park Academy and Pacific Conservatory of Music and Art, respectively. The library and laboratory facilities are such as to enable students to pursue thoroughly all the regular college courses and to do the fundamental work looking toward higher special training in the professions, teaching, and engineering. Entrance and graduation requirements are equal with those of the other colleges and universities of the state. The college faculty numbers twenty-two. The enrollment in the college is 134, and in College Park Academy and Pacific Conservatory 210, making a total of 344. J. W. H.

PACIFIC UNIVERSITY, FOREST GROVE, OREGON. — Was organized in 1854 under Congregational auspices, but it is not subject to denominational control. Tulatin Academy, out of which the college developed, was granted a charter in 1849. Rev. Sidney H.

Marsh, D.D., was its first President and remained at the head of the institution for twenty-six years. Pacific University is frankly a college and makes no university pretensions, but because of legal difficulties is still required to use the original title. It requires fifteen units for entrance, and a full four-years' course for the Baccalaureate degree. It confers the degree of M.A. for one year of graduate work above the A.B. course and the presentation of an acceptable thesis. The total value of campus and buildings is \$198,000 and the cash endowment is \$245,000. The faculty numbers twenty-seven, and there are 250 students in all departments. W. W. P.

PACIOLI, LUCA (also PACIUOLO) — Mathematician, known from his birthplace as Fra Luca di Borgo San Sepolero. He was a prominent writer on mathematics about the year 1500. The name appears in one of his works as Pacioli, but the family name was Paciuolo, so that both spellings are given in the histories of mathematics. He was born at Borgo San Sepolero, in Tuscany, about 1445, and died in 1515. He was the first man in modern times to publish in printed form a noteworthy general treatise on mathematics, the *Sūma de Arithmetica Geometria Proportioni et Proportionalitate*, written in Perugia in 1487 and published at Venice in 1494, a second edition appearing posthumously in 1523. He went to Venice in 1464 and acted as a tutor in the household of a wealthy merchant, remaining there until 1471, when he went to Rome. About this time he entered the Minorite order, but continued his work as a teacher. In 1476 he wrote a work on mathematics for his pupils in Perugia, but it was never printed. In 1481, while teaching at Zara, he wrote another, but that is also lost. It is probable, however, that the essential features of both of these works appeared in his *Sūma* of 1494. From 1471 to 1476 he traveled extensively (*per diversi paesi ce convenuto peregrinando*, as he says) and may possibly have gone to the Orient. His *Sūma* is a large treatise, containing about all that was known of algebra, geometry, and arithmetic at the time it appeared. From 1496 to 1499 he was teaching in Milan, and in 1497 he wrote his *Divina Proportione*, publishing this at Venice in 1509. He also published an edition of Euclid (Venice, 1509). Other manuscripts of his are extant, but no others have been published.

PADERBORN, UNIVERSITY OF, WEST-PHALIA, PRUSSIA. — Established by Prince-Bishop Theodore of Fürstenberg in the year 1614. Like a number of other German universities, it owed its origin to a Jesuit college, such an institution having been founded in Paderborn in 1592. The university consisted only of a theological (Catholic) and a philosophical faculty, and belongs to the group of the institutions of higher learning that were disbanded in the early part of the nineteenth century, its doors being closed in 1819.

PADUA, UNIVERSITY OF, ITALY. — A *studium generale* was established at Padua in 1222, although it may be that law was taught there in the twelfth century. The immediate cause of the origin of Padua University was the secession of the students and professors as a result of dissensions with the city authorities. But that matters were not so satisfactory at Padua is indicated by a contract of 1228 between students and the city authorities to move to Vercelli. From this it appears that already at that date there were from 2500 to 3000 students at Padua, and this university was not affected in spite of the migration of a number to Vercelli. Between 1237 and 1260 a decline set in, and the university practically ceased to exist owing to the tyranny of the Ezzelini. A second migration from Bologna gave Padua a new start, statutes were drawn up, and a Papal Bull was granted in 1264 by Urban IV and was confirmed in 1346 by Clement IV. The municipal authorities contributed largely to the success of the university. The most important faculty was for a long time the legal; grammar, rhetoric, and medicine grew up gradually. In 1363 a theological faculty was sanctioned by Pope Urban V. Padua reached the highest point of her fame and success in the fifteenth and sixteenth centuries and even surpassed Bologna. It was an important center of the Renaissance studies and on that account attracted many foreign students, although the law students still predominated. In the eighteenth century the university declined rapidly and did not attain to any importance until the nationalization of Italy, although efforts were

made to revive it under the Austrian rule. There are at present the following faculties: law; medicine and surgery; mathematical, physical, and natural sciences; philosophy and letters. Besides these there are schools of engineering and pharmacy, and a course for training of teachers. The enrollment in 1910-11 was 1383, of whom 400 were in the faculty of law.

PÆDAGOGIUM. — See HALL.

PAGE, DAVID PERKINS (1810-1848). — Leader in the normal school movement and author of the most popular educational book published in the United States; born in Epping, N.H., the 4th of July, 1810. He got his schooling in the district schools of New Hampshire and at the Hampton Academy. At nineteen years of age he began his career as teacher at Newbury, Mass., and three years later he was elected vice-principal of the high school at Newburyport. His address on "Duties of Parents and Teachers," read before the American Institute of Instruction in August, 1838, Horace Mann declared the finest educational paper that had been read before that association during its eight years of existence. During the next six years Page contributed regularly to the *Common School Journal* edited by Horace Mann, and took an active part in the various educational meetings organized by Mr. Mann in Massachusetts and Henry Barnard in Connecticut.

With the opening of the normal school at Albany (the first in New York) in 1844, Page was selected as principal upon the hearty recommendation of Mann and Barnard. But the new institution met with a storm of opposition. "The newspapers ridiculed and denounced it. They invented all kinds of falsehoods about Mr. Page, and in many ways misrepresented the school and its work. The politicians were against it, and the teachers of the state had no love for the school or its Massachusetts principal." With each session of the state assembly the politicians endeavored to abolish the school; but Mr. Page visited all the chief cities of the state and explained the purpose of the normal school. "His presence carried conviction and won allegiance. His speeches turned the tide, and public sentiment favored the school." But he exhausted his physical powers in his efforts to save the school, and he died in his thirty-eighth year on the 1st of January, 1848.

Mr. Page took an active part in institutes

and other educational gatherings in New York State as he had previously done in Massachusetts. Horace Mann remarks concerning his public lecturing, "He possessed that rare quality, so indispensable to an orator, the power to think standing on his feet and before folks."

Besides the essay on "Duties of Parents and Teachers," 6000 copies of which Horace Mann had printed and distributed to the teachers of Massachusetts, Mr. Page's only published writing is his *Theory and Practice of Teaching*, published in 1847. "No other book on the subject of education," writes Albert E. Winship, "has been read by so many American teachers through so many years." At the time of the expiration of the copyright (1889) more than 100,000 copies of the book had been sold; and with the expiration of the copyright three new American editions appeared. Probably no other American book on education has so much claim to be considered a classic.

PAIN. — This is now regarded as the sensation that arises on stimulation of a particular point or nerve end on the skin. It was earlier thought to arise from overstimulation of any sense organ. According to von Frey there are on the average from 100 to 200 pain spots to the square centimeter. They are about ten times as numerous as the pressure spots, and are about 1000 times as difficult to excite. That pain spots are distinct has been shown, not merely by mapping the spots, but also from the fact that there are certain tissues (the conjunctiva and cornea) where there are pain spots but no pressure spots, and others (the inside of the cheek) where there are pressure spots but no pain spots. Von Frey conjectures that the free nerve endings are the sense organs of pain.

PALMER, ALICE FREEMAN (1855-1902) — President of Wellesley College; born at Colesville, N.Y., the 21st of February, 1855. She entered the Windsor Academy in 1865 and graduated in 1872. That year she entered the University of Michigan, where she graduated in 1876. Miss Freeman was called to Wellesley College as professor of history in 1879; two years later she was elected vice president of the college, and in 1882 she was chosen president. This position she held until her marriage with Professor George H. Palmer of Harvard University in 1887. From 1892 to 1894 she was dean of the women's department of the University of Chicago.

Mrs Palmer held numerous incidental educational posts during her brief but brilliant career. From 1889 to the time of her death she was a member of the State Board of Education of Massachusetts and gave considerable time to the reorganization of the state normal schools. She was active in the councils of the Collegiate Alumnae Association. From 1888 to the time of her death she was one of the trustees of Wellesley College. She was one of the directors of the Columbian Exposition at Chicago in 1893. She was president of the Woman's Home Missionary Association, and a member of the board of trustees of the International Institute for Girls in Spain.

PALSGRAVE, JOHN (d. 1554). — English divine, who enjoyed the favor of Henry VIII and was appointed by him tutor to Princess Mary (the king's sister) and later to Henry Fitzroy, Duke of Richmond (the king's natural son). Palsgrave had studied at Cambridge, Paris, Louvain, and Oxford. He was the author of the earliest work giving the rules for the pronunciation and grammar of the French language and a French-English and English-French dictionary. The title of the work, which appeared in 1530, and was printed by Richard Pynson, was *Lesclaircissement de la Langue Francoyse, compose par maistre Jehan Palsgrave, Angloys, natif de Londres et gradue du Paris*. The work is still of value as a storehouse of obsolete English words and phrases. Another pioneer work of Palsgrave was the translation for school use of a Latin play into English. This was the *Acolastus* of G. Fullonius, published under the title *Joannis Palsgrave, Londoniensis, Ecphrasis Anglica in comediam Acolasti*. The *Comedy of Acolastus translated into our English tongue after such manner as children are taught in grammar school, first word for word, as the Latin lieth, and afterwards according to the sense and meaning of the Latin sentences*; etc. In the dedication (to Henry VIII) Palsgrave attacks the prevailing method of translating good Latin into bad and barbarous Latin, "instead of pure English words and phrases." He wishes to see "such an established marriage between the two tongues as may be . . . an incredible furtherance to attain the pure Latinity by."

PAMPHLETS. — See **TRACTS, EDUCATIONAL**.

PANAMA CANAL ZONE. — Little or no facilities were provided for education in the Canal Zone before the work was taken over by the United States. Spanish schools had existed at Panama and Colon, and under the French a few colored teachers had been imported to look after the children of the laborers; but as the French had no right of government in the district, little progress was made. With the arrival of Americans, however, the demand for school facilities soon made itself felt, but little progress could be made before more pressing needs such as buildings for dwelling houses were satisfied. By 1907 there were twenty-five school buildings (eleven for white and fourteen for colored children) in nine-

PANAMA CANAL ZONE

teen towns, with twenty-one white and eight-
een colored teachers. By 1909 the number
of schools had increased to twenty-nine in
twenty-one towns (twelve schools for 675
white children, and seventeen schools for 1417
colored children). There were in 1909 thirty-
five white teachers, all with two or more years
of successful experience in the United States or
the Canal Zone beyond the four years of high
school and two of normal school. The
teachers are divided into four classes, receiving
respectively \$50, \$60, \$90, and \$100 salary
per month. In the colored schools teachers
are almost all obtained from Jamaica and
long to the third and fourth classes.
Schools are under the control of the Division
of Schools which appoints a superintendent.
Two supervisors, one for primary grades and
one for grammar grades and high schools, are
charged with the duty of unifying the standards
in all the schools and keeping up the high
standard. The school term is from
October 1 to June 30, with
intermissions. In 1909 medicine
was introduced for white children.
The government supplies free textbooks.
School libraries were
in 1907 from the proceeds of
amusements. The curriculum
consists of reading, English,
arithmetic, geography, history, music,
Spanish (from the fifth grade),
and school gardens were in-
stituted to add agriculture
to the curriculum.

PAPPOS, or PAPPUS. — One of the prominent geometers on geometry among the later ancients. Little is known of him save that he lived in the fourth century of our era. His most important work was his *Mathematical Collections* (*Μαθηματικῶν συναγωγῶν βιβλία*), a treatise which is supposed to have been in eight books, but of which only six are extant. The first Latin edition was published in 1588, and with changed title in 1602. There was a new edition published at Bologna in 1660. This work, of various geometrical problems, including the duplication of cubes, the trisection of angles, the quadrature of the circle, and the duplication of areas of solids, the conoids, and mechanics.

PAPYRUS TESTAMENT, PEDAGOGICAL EDUCATION.

PARALLEL PHYSICAL. —
 Both in philosophy and in the discussion of the physical sciences. In philosophy it has two branches, the physical and the metaphysical. He uses the term in a broad sense, but it is not curved in the physical aspect of the body, but it is curved to the metaphysical aspect of the body.

PARALLEL
 PAPER

PARALYSIS

since such a transformation would tend to reduce the amount of physical energy in the world. In view of the attitude of the physicists in this matter, psychologists have found some difficulty in accounting for the relation between mental processes and physical facts. They have, therefore, been content to recognize that there is a parallelism between the two groups of phenomena and have been willing to postpone or leave as entirely insoluble the determination of the exact nature of this relationship. In this form, the doctrine of psychophysical parallelism simply evades the difficulties above referred to. Mental facts and physical facts can now be discussed under this general doctrine without going into the metaphysical problem of the ultimate relation between the two sets of facts.

Several questions might arise at this point. Is every physical fact always paralleled by some mental fact? Those who answer this question in the affirmative and hold that there is a complete parallelism between the two sets of facts are sometimes called "panpsychists." On the other hand, most psychologists are satisfied to limit the assumption of parallelism to those cases in which there is some obvious psychological advantage in the study of this parallelism. Sensation processes and thought processes, which depend upon cerebral activity, are evidently included under such cases. Whether the vibrations of the molecules in a stone are accompanied by conscious processes is a purely speculative problem which has no significance for the psychologist.

Certain writers have confused the metaphysical and the psychological interpretation of this doctrine, and have attempted to make it appear that the psychologists who wish to avoid by the adoption of this doctrine all metaphysical discussions are in reality denying certain metaphysical relations such as relation of causation. Such a contention is, however, wholly unjustified, as will be found by a reference to the writings of Wundt who is one of the foremost defenders of this doctrine in psychology. (See his *Outlines of Psychology*, p. 360.) C. H. J.

PARALYSIS.—The lack of the ability to move one or more parts of the body. Those paralysees are of single muscles, of groups of muscles, or of small or large segments of the body. The paralysis may be the result of injuries to or destruction of very different parts of the nervous system. There are those

PARANOIA

which result from the injury or destruction of the peripheral nerves; those which result from the section or disease of the anterior roots of the spinal cord; those due to disease or injury to the spinal cord itself; and those which are due to the destruction of parts of the brain.

The paralysees are of great interest on the educational side, since they limit the activity and, consequently, mental capacity of the child. The paralysees of infantile type (those which are due to injury of the nerves in the arm or legs produced at the time of birth) may not be discovered for some time, until all power or possibility of regeneration of the nerves has passed away. Besides these, however, the paralysees in childhood are mostly curable, since they are due most often to injuries of the external part of the brain, and of the peripheral nerves, many of which may be treated with good effect by surgical means. The education of the paralyzed must be carried on in quite a different way from that of normal individuals; the means must be adapted to the individual equipment. The child with right arm monoplegia or with an hemiplegia cannot, under any conditions, be taught to write with the right hand, although some gross movements of that side may be possible. Insistence on a special form of enunciation is also out of the question with certain kinds of facial paralysis. Each case, however, must be considered in itself, and it is impossible to lay down any special rules to apply to every type of paralysis.

Very often anesthesia (*q.v.*) gives much the same result as the paralysis itself; because of the lack of the sensory stimulation, parts may not be moved, they become paretic and sometimes immovable. It is for this reason that abnormal individuals of this class should be given a careful medical examination, and the teacher should have all of the facts, medical as well as educational, upon which to base her training methods.

Paralysis is sometimes used as the equivalent of general paralysis of the insane, or paresis (*q.v.*), but is not correctly used in this sense. The term palsy is often used as the equivalent of paralysis, especially when the nerves are involved. S. I. F.

See **INFANTILE PARALYSIS**.

PARANOIA.—A mental disease characterized by systematized delusions and, except in this particular, exhibiting no mental degener-

ation. A number of years ago the major part of those admitted to hospitals for the insane were diagnosed paranoiacs, but most of these were undoubtedly suffering from other diseases in which similar symptoms are found. The paranoid (or paranoia-like) complex consists of the systematized delusion (*q.v.*), and this is present in many cases of dementia precox, or alcoholism, of manic-depressive insanity, and even of paresis. The distinguishing characteristics of paranoia are the chronicity and the lack of mental deterioration, and these conditions are found in only a few cases showing the paranoid complex. Since the term paranoid has not been discussed in the article dealing with dementia precox (*q.v.*), and on account of its widespread use, it needs further consideration.

As in most of the psychoses, there is at first a period of depression, nervousness, and vague feelings of discomfort. This stage is followed by self-introspection, and by endeavors to bring the actions of others into line with these feelings. This leads to the reference of one's feelings, actions, and thoughts to others. Many paranoiacs do not passively undergo the believed persecutions, but appeal to the neighbors, to the police, etc.; they go to law; they commit crimes and breaches of the peace. Throughout most of this period there are hallucinations of hearing; voices often tell the patient what to do, what power and position he has, etc.

In the usual paranoid state the systematization is less complete. True paranoia begins early and is progressive. Paranoia states may occur at any time, and may disappear when the occasion for the beliefs disappears. It is now believed by some that the paranoia state, in all forms, depends upon peculiar characteristics of the individual reaction, viz. the introspective, shut-in characteristics, and that these give a cue for the understanding of the abnormality. Whether or not this be the true explanation of all cases, it undoubtedly plays a part in many, and the conception is helpful in directing attention to the relatively frequent child who may need more of the teacher's effort in a social way. Such children should be encouraged in every way to come out of themselves, and to become a part of the community; they should be encouraged to take part in mass plays and in games in which they may act successively as leader and subordinate, and their attention should be attracted largely to things outside of themselves. S. I. F.

PARENTHOOD. — See PARENTHOOD, EDUCATION FOR.

PARENTHOOD, EDUCATION FOR. — During the early stages of the child-study movement, there was much debate regarding the needs of parents for the proper upbringing of their children. Considerable literature appeared on the general topic, "Child study for parents," in which the view was presented that the parent's relation to his children must be *naïve* for the most part. The terms "instinctive," "spontaneous," and "common sense" appear very frequently in this literature. Nevertheless it was recognized that it would be of advantage to parents if they could be made familiar with the more important requirements for the healthful physical development of children, and for their moral training. At the same time, many persons who were not in sympathy with the new movement declared that any deliberate study of his child would be a handicap rather than a help to a parent, since it would make him more of an observer and a student than an affectionate guide and counselor. From 1890 to 1895 a number of prominent educational men denounced the efforts being made to induce parents to form child-study societies with a view to acquiring what was known regarding the nature of the child and his needs for sound development. Many maintained that parents would derive greatest help from the pursuit of such "cultural" subjects as history, literature, and art, which would enable them in their association with their children to give them the inspiration which was said to emanate only from these sources. On the other hand, the men and women who had inaugurated the child-study movement were, and still are, most diligent in their attempts to encourage parents as well as teachers to study the child in some such way as they would investigate any object with a view to determining its nature and the best methods of dealing with it. As a consequence of these efforts, there is to-day a widespread belief in this country, and also in England, and to a lesser extent in Germany, France, and Italy, that all who deal with children would be aided in their work if they could be made familiar with what is established respecting the native tendencies of the young, and their physical, intellectual, and social needs. This interest, as it is related to education for parenthood, is expressed in a variety of institutions and organizations.

Institutional Education. — In our own country and in England there has been a considerable demand from various parents' organizations

during the last decade that studies dealing with requirements for efficient parenthood should be offered in high schools, normal schools, colleges, and universities. There are as yet, however, no courses in any of the groups of institutions mentioned which aim directly at training for parenthood. An examination of the curricula of many high schools in all sections of the country, and an inquiry made of a large number of the principals of these schools, indicate that pupils therein have manifested no interest in courses for parenthood, and would probably not pursue them if they were offered. In a very few instances, where high schools attempt to train teachers, certain topics relating to the nature of the child are discussed in the courses in psychology. But it is probable that the students in these classes acquire little, if anything, which relates specifically to the problems of parenthood.

An examination of the curricula of the normal schools throughout the country shows that no attention is given to effective education in the home. The psychology presented in these schools is for the most part analytic, adult psychology. In eighteen normal schools, courses are described which deal with the development of the child mind, as distinguished from the functioning of the adult mind. But this instruction refers particularly to the needs of the teacher rather than to those of the parent. And as in the high school, so here the instruction given in methods of teaching is not at all suited to the conditions, opportunities, and needs in the home.

One might expect that some attention would be given to the study of parenthood in women's colleges; but with two exceptions, possibly, there is no work whatever offered in these colleges bearing directly on any of the problems of parenthood.

The Mississippi State Industrial College (for women) at Columbus has begun to reorganize its curriculum and its work with a view to training girls specifically for home responsibilities. A plan has been projected in which every girl will be required to pursue courses pertaining to the nature of children, their physical care and intellectual development, and their ethical and moral training. The plan provides for cottage life for the students, so organized that each girl before she graduates will be required to manage a cottage in all details as a typical home, including the care and culture of childhood. This work will be required before a degree will be given.

While no work in the universities anywhere is designed mainly as a training for parenthood, there are still courses which relate to the nature and education of the child, in the home as well as in the school. Seventy-one important colleges and universities at present offer well-organized courses under such titles as "child study," "genetic psychology,"

"psychology of the child," "mental development," and "adolescence." In several universities a study of the child from birth onward is included in the general subject of "principles of education." Although the emphasis in these courses is not laid upon the parent's rôle in the education of the child, nevertheless much of what is presented relates quite directly to parental problems. It should be added that a large proportion of the colleges and some of the older universities offer no work relating to child nature. Even in the courses in psychology, no reference is made to child psychology.

An inquiry made concerning the interests of the students who elect such subjects as "child study," "mental development," and the like, shows that these courses are not chosen primarily as a preparation for parenthood. They are conducted, with but rare exceptions, in the department of education, and are pursued by students who are candidates for teachers' positions. It is worthy of remark that in the domestic science departments of the agricultural colleges, in which much attention is given to the making of a home in respect to the purchase and preparation of food, the sanitation and decoration of the home, and so on, little if anything is said regarding the traits and education of children. Such questions, however, are frequently considered when these agricultural colleges hold conventions of women who live on the farm.

In all the kindergarten training colleges courses are conducted which pertain to the nature of the young child, and the method of his instruction and entertainment. For the most part these courses are presented in the spirit of Froebelian philosophy and in metaphysical terminology. It is probable that on the theoretical side they do not deal very closely with the actual manifestations of child life in the home; but on the practical side they appear to present helpful methods in directing the child's activities. In this way they may be of substantial aid to a parent in the training of his child. In the Chicago Kindergarten College a definite course for parents has been organized for the purpose of discussing matters pertaining to the spiritual and physical nurture of children, such as the direction of the child's activities in the home, children's failures and how to utilize them, the treatment of the child's questions, the meaning of imitation in the child, and so on. Practical lessons are given on the value of stories, games, and handwork in the development of the child. Lectures are also given on eugenics, including heredity, sex development, infant mortality, and kindred matters. These courses are offered to mothers and students free of charge. Two hundred students were enrolled in these courses in 1911-1912. This work has attracted attention, not alone in Chicago, but in other cities also, and there is

PARENTHOOD

an indication that similar courses will soon be instituted elsewhere.

The Stout Institute at Menomonee, Wis., now a state institution, offers similar work. So far as can be ascertained, the Institute is exceptional in respect to the attention which is given to studies pertaining directly to parenthood.

It is of special importance to note that in several of the Chicago elementary schools "Little Mothers' Classes" are being conducted on Friday afternoons. The girls are taught the duties of motherhood, and, wherever possible, babies are used by nurses to exemplify the work. This work is done by the nurses who regularly visit the schools.

No courses are offered in educational institutions in any foreign country aiming directly at preparation for parenthood. Much is being accomplished in the study of child life in Germany, and to a less extent in France, England, and Italy; but most of what has been established has not yet reached parents at all. At the present moment, though, there is lively activity, in Germany and England especially, in the formation of societies and congresses for the dissemination of knowledge pertaining to the child.

The National Congress of Mothers. — Undoubtedly the most effective organization in the world to-day for the development of interest in the rational care and culture of the child in the home is the National Congress of Mothers, established in the United States in 1897. At the present time, this Congress has in the neighborhood of 75,000 members, distributed throughout the country, and the list is increasing rapidly. Nearly all the states have congresses affiliated with the National Congress. There has been organized under the Congress a National Parent-Teacher Association, and an International Congress on the Welfare of the Child. The latter Congress meets every third year, and it is designed as a medium for the dissemination throughout the world of the ideals for which the Congress of Mothers is working. The Parent-Teacher Association has become an integral part of the National Congress. In the original statement of the purpose of the Congress, emphasis was laid upon the aim of educating parents so that they might intelligently care for their children physically, and direct their spiritual development. Coöperation of the home with the school was also made prominent in the work of the Congress. Further, it was the purpose to promote the establishment of kindergartens, and to secure legislation which would adequately care for neglected and dependent children. It was stated that the Congress would seek to secure proper training of young people for the opportunities and duties of parenthood.

During its fourteen years of existence the

PARENTHOOD

Congress has worked effectively towards the accomplishment of these aims. As it has developed, it has broadened its original purpose, and it now gives attention to such matters as the establishment of juvenile courts (*q.v.*) and probation associations, the development of schools for teaching the deaf, the education of parents in respect to the evils resulting from child labor, propaganda with regard to the use of the schoolhouse as a social center, the establishment of public playgrounds, the introduction of manual training and domestic science into the school curriculum, coöperation with farmers' institutes for the betterment of children in the country, and the like. The Congress has also been active in the formation of parents' clubs and societies in foreign countries. In 1906 it established the *Child Welfare Magazine*, in which a prominent place was at first given to scientific literature dealing with child nature and the training of children. Latterly, however, there have appeared in the magazine articles of a more practical character, written usually by parents who have become distinguished for their helpful suggestions relating to the training of the young.

The affiliation of Parent-Teacher Associations with the Congress of Mothers has changed somewhat the original character of the latter, the tendency now being to give attention quite largely to questions pertaining to child welfare in its legal and social aspects, as well as to the care and training of the child in the home.

It is apparent that the National Congress of Mothers, through its great number of affiliated state congresses, local mothers' circles, parent-teacher associations, and its International Congresses on the Welfare of the Child will exert an increasing influence throughout the world for the betterment of child life, not only in the home, but also in the school and in the community. The chief problems presented to the Congress now seem to have reference to the scientific character of its work. It is seeking to make a scientific treatment of parental problems attractive to persons who are untrained in scientific methods and ways of thinking, and those who are directing its work appear to have the situation thoroughly in hand.

The Parents' National Educational Union. — This organization, modeled in considerable part upon the National Congress of Mothers, is an English society. The Union seeks to treat the development of the child and his training from the physical, mental, moral, and spiritual standpoint. It aims to reach fathers as well as mothers, and its efforts are not limited to the people of any class. It endeavors to collect and disseminate the best available information relating to the training of children and to bring about the coöperation of parents in any community for the interchange of their views and experiences. There

are many branches of the central Union; and while they are designed particularly for parents, still any person who declares his interest in education may enroll as a member. The organ of the Union is *The Parents' Review*. The Union has also established a library for the purpose of lending books and articles pertaining to home education to parents and any others who may be interested. Finally, it conducts a Mothers' Educational Course which is designed to be a reading course relating (1) to the methods of religious education, (2) the care and development of children in sickness and health, (3) the study of the principles and methods of education, and (4) particularly to the development in children of an interest in nature. The course is designed to be systematic, and to be completed by an examination.

Another English association similar in aim to the Parents' Union, but not so comprehensive in scope, is the Child Study Society, London, which concerns itself with the "scientific study of the mental and physical conditions of children, and also of educational methods." Its organ is *Child Study*.

International Congress on Home Education.

— In 1905 an International Congress on Home Education was instituted in Belgium under the direction of the Belgian government. At this first meeting twenty-four different governments were represented, and 1200 delegates were in attendance. About 250 specialists in the countries represented contributed papers pertaining to childhood and child welfare, and these were published in seven volumes. Although not circulated extensively in English-speaking countries, they have played a considerable rôle in developing in continental Europe an interest in the psychology, pedagogy, sociology, and biology of child life. Since the first International Congress, which was held at Liège, there have been two others, — one at Milan in 1906 under the patronage of the king of Italy, and the other at Brussels in 1910 in connection with the Universal Exhibition. It has just been decided to hold the fourth International Congress at Philadelphia, in 1914. The Congress consists of five sections: (1) The study of childhood, (2) the education of children, (3) abnormal children (4) various subjects relating to children, and (5) literature.

International Congress on Pedology. — As some of the members of the International Congress on Home Education believed that its scope was too comprehensive, there was established in 1911 at Brussels an international congress for the purpose of bringing together persons interested in the scientific study of child development. It is composed largely of psychologists, psychiatrists, educationists, and persons of kindred interests.

It is not at all improbable that during the

next few years most of the national and international congresses which are now being formed will become merged into two or three general organizations, which will centralize all the activities relating to the study of childhood.

Child Welfare Exhibits. — During the winter of 1910 an exhibit was held in New York for the purpose of showing in as concrete a way as possible by means of photographs, symbolic representations, lectures, and living demonstrations the actual conditions of child life, and practical methods of conserving the health and improving the morals of the young. The exhibit proved to be so successful that it was transported to Chicago, where it was enlarged and presented during the month of May, 1911. As a result of the success of these two exhibits, plans are in preparation for similar exhibits in a number of cities of the country. So far as can be ascertained, no vital criticism has been passed on the usefulness of such exhibits. It seems apparent that the general plan of exhibiting the facts of child life in a concrete, dynamic way will meet with increasing favor, and be adopted by communities in every part of the country.

These exhibits present pictorially and in living demonstrations facts pertaining to child life in the home, on the street, in the school, in the church, in the theater, in the public library, in clubs, in associations, on the playground, and in amusement halls. Lectures are also given by competent persons upon every phase of child life treated in the exhibit.

Educational Departments of Women's Clubs.

— Visitors to America from foreign countries generally express surprise at the thorough-going way in which the women here are organized for educational purposes. In most communities there is at least one woman's club, the purpose of which is to enable its members to participate in the intellectual, social, educational, and philanthropic activities of the community. Originally the women's clubs gave their attention largely to literary and artistic pursuits, but latterly they have undertaken to study in a careful way the life of the communities in which they are situated, with a view to suggesting improvements therein. These clubs are usually conducted under various departments, one of which is concerned with education. A program is prepared by the educational department at the beginning of the year which relates either to the training of children in the home, or to the improvement of educational conditions in the school and of child life in the community. In some instances the members pursue courses of reading in connection with the various topics discussed.

It seems evident that the influence of women's clubs is becoming constantly more potent for good in the betterment of conditions for the child in the home, in the school, and in

society. There is a developing conviction among the members of these clubs that the chief work of women should relate to child welfare. In some cities, only those departments of the women's clubs that are concerned with one or another phase of civic activity arouse much enthusiasm in the members. These clubs have already in many places secured important reforms in respect to the curriculum and the physical conditions of the schools, and the life of children in the community. They have secured public playgrounds, gymnasiums for the public schools, and similar reforms.

Parents' Meetings in Public Schools. — During the past decade, teachers in the public schools in every section of our country have been active in attempts to interest the parents of their pupils in the work of the schools, and in matters pertaining to the proper care of children. It is the practice in most places to give exhibitions or receptions to which parents are invited, and as a part of the program educational topics are discussed. From reports received, it is evident that the meetings have been successful in informing parents regarding new developments in school work, and in securing support from the community in regard to the extension of educational advantages, such as the establishment of gymnasiums, the improvement of the hygiene of public schools, the securing of playgrounds for school children, and the like. In this work it has been necessary everywhere for teachers to take the initiative; and so far as it has been possible to secure data for this article, it is apparent that the success of parents' meetings has been dependent almost entirely upon the efforts of teachers. However, responses received to a questionnaire regarding the value of parents' meetings in the public schools indicate that in communities in which these meetings have been held for several years parents are taking a more intelligent interest in the work of their children in school than they did formerly. Reports have come from a number of communities saying that as a result of the meetings parents now frequently visit the public schools, and cooperate with the teachers in securing needed improvements which require financial support from the community.

Eugenics Clubs. — There is beginning to be manifested in some communities a lively interest in the subject of eugenics (*q.v.*). In some cases the women's clubs have taken up a discussion of this topic. Eugenics clubs have been formed for the purpose of considering the requirements for the improvement of the race through the betterment of the conditions of childhood, both before and after birth. An examination of the programs of some of these clubs shows that the topics considered relate directly to problems of parenthood. In at least one state, Iowa, the Federation of Women's Clubs and the Mothers' Congress

have taken definite steps to make a careful study of the subject of eugenics. A woman physician has been sent abroad to find out what progress has been made there in the study of the subject. It is proposed to develop a method of "scientific scoring" of children in some such a way as horses, cattle, and corn are now scored in agricultural colleges. The physicians of the state worked out a standard which was applied to a large number of babies, and included items pertaining to height, weight, measurement, condition of teeth, of eyes, of nerves, and so on. Apparently the exhibit at the Iowa state fair attracted favorable attention, for it has been repeated in one form or another in a number of communities in the state. M. V. O'S.

PARESIS.—In a general sense a muscular weakness. It is also a name of a special neuro-mental disease which is popularly spoken of as "softening of the brain," and in a scientific way as "dementia paralytica" or "general paralysis of the insane."

The use of the term in its general sense indicating muscular weakness is that which is most general in neurological writings. The weakness may result from a variety of physiological and anatomical conditions. Those which are of most common occurrence, and which, consequently, are best known, are the pareses from disuse. When an individual does not utilize certain muscles, these muscles decrease in strength and also in coordination ability. Certain muscles of the body are commonly parietic, and practically paralyzed. The muscles moving the scalp and the ears are examples. They are seldom utilized; and when one endeavors to move the ears, for example, it is found that the movement is slight and of little force. The paresis due to disuse may be ameliorated by training, and a few attempts at moving the scalp and the ears will show how soon these muscles may be trained and how readily they acquire a considerable degree of force, because of the exercise.

A paresis may result from disease of the nervous system, especially from certain cerebellar affections. It is sometimes found in neurasthenia (*q.v.*), in psychasthenia (*q.v.*), and in hysteria (*q.v.*).

Although one of the principal methods of treatment of muscular weakness is educational, the presence of the condition is of much greater pedagogic interest. Exaggerated or premature feelings of fatigue, accompanied by an apparent muscular weakness, is evidence of one of the many diseases of the nervous system, and in this state no child is fit to carry on the ordinary school work. It is criminal to attempt to stimulate the child under these conditions; he should be treated as one who is ill and who needs rest and care more than the mental and physical exercise of the school day. Paresis in the sense of dementia paralytica is a disease appearing between the third and fifth decades. The disease is one in which the dementia becomes profound very rapidly, and death usually ensues within two years after the onset of the symptoms. S. I. F.

PARESTHESIA.—An hallucination in the fields of the skin, muscle, joint, or organic senses, but commonly of a qualitatively different character from the normal perception of stimuli to these sense organs. Most of the paresthesias have not been analyzed psychologically, although they have a decided importance on account of their relation to the poorly understood organic sensations. A common paresthetic experience is that of the foot or leg "going to sleep." This is caused by pressure on the nerve trunks in the upper part of the leg or at the angle of the knee, and the sensation or perception is referred to the lower part of the leg. The feeling of the presence of an amputated limb is another similar paresthetic condition, due to some irritation in the nerve fibers which formerly supplied the limb that was amputated. The most common paresthesias are as follows: feelings of weakness, of debility, of faintness, of oppression, of weight or constriction, of tightness in the chest and inability to breathe, of heart constriction, of heart throbbing, of sinking, of flying, the bearing down feelings, formication (feeling of crawling ants), itching, tickling, (at times), furry feelings, numbness, tingling, some burnings, chilliness, the feeling of a part of the body "falling asleep," and the so-called girdle sensations. Many of these paresthesias are found in normal people, and cannot be considered to be distinctly pathological, although they reach their height and intensity in pathological conditions of the nervous system. The analyses of the paresthesias that are made indicate clearly the artificial division between the normal perceptions (*q.v.*), illusions (*q.v.*), and hallucinations (*q.v.*). S. I. F.

PARISH AND PARISH SCHOOLS.—See PAROCHIAL SCHOOL SYSTEM AND PARISH SCHOOLS.

PARISH, ELIJAH

PARISH, ELIJAH (1762-1825). — Author of geography texts; graduated from Dartmouth College in 1785, and engaged in the ministry of the Congregational church. He published *New System of Modern Geography, Sacred Geography*, and with Jedediah Morse (*q.v.*) *Gazetteer of the Eastern and Western Continents* (1802). W. S. M.

PARISH SCHOOLS AND PAROCHIAL SCHOOL SYSTEMS. — The schools under the control of the church, and attached in some manner to the local system of parish churches. The historical position and character of these schools is discussed under a number of topics. The most important of these are **CHURCH SCHOOLS**; **BISHOPS' SCHOOLS**; **CANON LAW AND EDUCATION**; **MIDDLE AGES, EDUCATION IN**; and the **REFORMATION AND EDUCATION**. Previous to the Reformation the parish school was the most important and in many places, if not entire countries, practically the only elementary school. After the Reformation, the elementary school continued to be a parish school in most countries until the nineteenth century. In England it was a parish school in fact as in name, in that it was essentially a church-controlled institution. In other countries the school retained the name, the church retained much of its influence, but the authorized or legal control lay in the state. The development of these schools into state systems is treated in the important sections in the articles on the various national systems. See especially the articles on **ENGLAND, EDUCATION IN**; **SCOTLAND, EDUCATION IN**; **GERMANY, EDUCATION IN**. At the present time the parochial school, supported in whole or in part by the state, and controlled in whole or in part by the church, exists in many countries, especially those of dominantly Roman Catholic affiliation.

The parochial school becomes a problem especially in those governments which, like the United States and France, have severed completely the relation between Church and State and have removed substantially all state contribution to church educational efforts. Even in these countries the severance of these ties has not settled the problem connected with the question of church schools. For the recent experience and present status in France, see the article on **FRANCE, EDUCATION IN**. For the United States, the experience and present status on the legal side is discussed under **BIBLE IN THE PUBLIC SCHOOLS**. The pedagogical aspect is dealt with more directly in the articles on **MORAL EDUCATION** and **RELIGIOUS EDUCATION**. There have, however, grown up actual parochial school systems of great extent entirely independent of the public school system. While the chief of these is that of the Roman Catholic Church, several of the Protestant denominations support elementary schools, and one, at least, —

PARKER, FRANCIS WAYLAND

the Lutheran, — has developed an extensive system. This is given in outline in the article on **LUTHERAN CHURCH AND EDUCATION**. The administrative aspects of the parochial school system of the Catholic church and the general position of that church regarding the relations of the public schools and the parochial school systems is given under the caption, **ROMAN CATHOLIC CHURCH AND THE PUBLIC AND PAROCHIAL SCHOOL SYSTEMS**.

The term "parish" is also used in the state of Louisiana for what is elsewhere in the United States termed "county," and is thus used in connection with educational administration. (See **LOUISIANA, EDUCATION IN**.)

PARK COLLEGE, PARKVILLE, MO. — A coeducational institution founded in 1875. Academic, collegiate, and music departments are maintained. The entrance requirements are fifteen units of high school work. The degrees of B.A. and M.A. are conferred in course. The enrollment of collegiate students in 1911-1912 was 227. The faculty consists of twenty-four members.

PARKER, FRANCIS WAYLAND (1831-1902). — American educational reformer; born at Bedford (now Manchester), N.H., Oct. 9, 1837. He received the rudiments of his education in the district schools and at a country academy. Later in life (1872-1875) he spent three years in study at the University of Berlin, Germany. From his sixteenth to his twenty-first year he taught in the district schools of New Hampshire. In 1858 he became principal of schools at Carrolton, Ill. With the outbreak of the Civil War he entered the service of the federal army, and before the close of the war had risen to the rank of colonel. From 1865 to 1868 he was principal of a grammar school at Manchester, N.H., and the next four years he taught in the normal school at Dayton, Ohio. Upon his return from Germany in 1875 he was elected superintendent of the schools at Quincy, Mass., which position he held for five years. For an account of his labors during this period, see under **QUINCY MOVEMENT**. From 1880 to 1883 Colonel Parker was one of the supervisors (assistant superintendents) of the schools of Boston. From 1883 to 1899 he was principal of the Cook County (Chicago) Normal School. In 1899 he accepted the principalship of the Chicago Institute, a pedagogic institution founded by Mrs. Emmons Blaine for the scientific training of teachers. One year before his death, this institution became the School of Education of the University of Chicago.

No American educator in modern times has done so much to modify and enrich the course of study in elementary schools. He was a lover of childhood and he had the insight to see educational problems from the standpoint of the child. He possessed extraordinary

personal powers, and his own enthusiasm and earnestness were always contagious. These qualities enormously increased the attendance at the Cook County Normal School. Students flocked hither from all parts of the country, and particularly from the Middle West; and the enthusiastic and scientific teachers that he trained have done much to bring about the educational uplift of our own day. His success was due to his zeal and fondness for children, and open-mindedness to whatever came to him from the world outside.

His educational publications include *Talks to Teachers, How to Study Geography, Course in Arithmetic, Talks on Pedagogics*, and a series of geographic readers entitled *Uncle Robert's Geographies*. For one year (1883-1884) he edited a monthly educational journal, *The Practical Teacher*. This journal contained essays by himself and his colleagues in the Cook County Normal School on the various aspects of elementary education. W. S. M.

PARLIAMENTARY EDUCATION COMMISSIONS, ENGLAND.—The intervention of the English Parliament in national education through the agency of Royal Commissions forms a very important side of the history of English education. The earliest education commission was a body appointed to carry out the suppression of monasteries. (See REFORMATION AND EDUCATION.) The second commission was that appointed under the statute for the abolition of chantries in 1547 (1 Edw. VI. 14). (See CHANTRY SCHOOLS.) The chantry commissioners missed a superb opportunity to reconstruct a system of education from the medieval material that was in their hands, though some of the old

schools were refounded (see the *Yorkshire Chantry Survey*, Surtees Society, 1892, by William Page). The third commission was appointed under Statutes 39 Eliz. 6 and 43 Eliz. 4 and 9 whereby commissioners for charitable uses were appointed to deal with the misemployment of charitable gifts. This body proved very ineffective in consequence of there being a statutory right of appeal from its decisions, but it in fact reformed thirty-three important schools between 1601 and the beginning of the nineteenth century. The commission was abolished by statute in 1888. (See CHANCERY, COURT OF.) In 1649 the Commonwealth Parliament appointed a large commission to deal with education in Wales and Monmouthshire. The commissioners were intended to exercise both ecclesiastical and civil powers over schoolmasters. (See COMMONWEALTH IN ENGLAND AND EDUCATION.) We may note in passing that in 1687 a high commission was appointed by the Crown to deal with the obstinate refusal of the Universities of Oxford and Cambridge to admit Roman Catholics to University privileges, while in October of the same year a special commission was appointed to exercise visitatorial jurisdiction over Magdalen College, Oxford, and secure Roman Catholic predominance in the College. In 1695 the Greenwich Hospital Naval School was founded by a Royal Commission aided by the Register Act of 1696 (7 and 8 Will. III. c. 21). In 1788 the Irish Parliament passed an Act providing for the appointment of a Commission to consider the state of Education in Ireland (25 Geo. III. c. 15). In 1806 the Imperial Parliament passed an Act (46 Geo. III. c. 122) to inquire into "the general funds and revenues granted for the purposes of education, and into the state and conditions of all schools in Ireland." The first chairman of this commission (which presented fourteen Reports between 1806 and 1813) was the sixth Duke of Bedford, the father of the famous educational statesman Lord John Russell (*q.v.*). In 1824 another Irish commission was appointed that presented nine Reports. In 1831 a Permanent Irish commission on education was appointed and this commission received royal charters in 1845 and 1861. (See IRELAND, EDUCATION IN.)

In England a select parliamentary committee was appointed in 1816 to "enquire into the Education of the Lower Orders" which issued a report dealing with London in the same year. It was reappointed in 1818 and reported on the whole kingdom and declared that "the anxiety of the poor for education was daily increasing" in town and country alike despite the "neglect and abuse" of educational foundations and the fact that the education societies almost wholly confined their efforts to the great towns. The Committee also dwelt on the growing religious tolerance in the schools. The conscience

clause (*q.v.*) was in fact already in operation. The committee advocated different methods for town and country; in towns a system of aiding schools by building grants (the system adopted in 1833) and in helpless country districts a system of practically rate supported free parochial schools (the system adopted in 1870). The report is a document of the first importance in the history of English education. This committee succeeded in passing an act in 1818 (58 Geo. III. c. 91) appointing commissioners to inquire into educational charities, who were appointed and reappointed until 1837. This commission dealt with endowments of the total value of £1,209,395. In 1835 a select committee recommended a permanent board of charity commissioners. In the same year the Poor Law Commissioners appointed under the Poor Law Act 1834 regulated the education of the pauper children. (See POOR LAW EDUCATION.) On August 17, 1833, the first parliamentary grant for education was voted. On June 4, 1834, a select committee of the House of Commons on education was appointed and a report consisting of evidence was issued on August 7. On March 3, 1835, a further select committee on education was appointed which reported with evidence only on August 3. On July 14, 1835, a select committee was appointed "to inquire into the best means of extending a knowledge of the Fine Arts and of the principles of Design among the people — especially the manufacturing population of the Country." The report of this committee (and of another formed in 1849) led to the formation of the Science and Art Department, which was brought under the Education Department in 1856. A third select committee on education was appointed on Nov. 30, 1837. It reported on July 13, 1838, and pointed out that voluntary effort alone was giving anything "worthy the name of Education" in large towns. The condition of the children in these towns was very serious, as they began work at the age of nine years. The position demanded, in the view of the committee, "some strenuous and persevering efforts to be made on the part of the Government if the greatest evils were not to follow." The committee insisted that daily educational provision must be made for at least *one eighth* part of the population; that special provisions must be made in poor districts; that the Treasury Grant System must be extended. On April 10, 1839, a permanent committee of the Privy Council was appointed to deal with National Education. This body by an Order in Council of February 25, 1856, became the Education Department, and this Department by an Act of 1899 became the present board of Education. In 1849 another Royal Commission on Charities was appointed under Lord Chichester which reported that "the evils and abuses are still in existence to a very wide extent, and no sufficient remedy has yet

been provided for this correction" and again recommended a permanent body of Charity Commissioners. These commissioners were appointed by the Charitable Trusts Act of 1853, and their powers have since been completely regulated by Parliament. By the Education Act, 1899, the powers of the commissioners over educational endowments were transferred to the Board of Education.

In February, 1858, on the motion of Sir John Pakington, a Royal Commission, the Newcastle Commission, was demanded by Parliament "to inquire into the present state of popular education in England, and to consider and report what measures, if any, are required for the extension of good and cheap elementary instruction to all classes of the people." The commission was gazetted on June 22, 1858, and reported (under the presidency of the Duke of Newcastle) on March 18, 1861 with no less than fifty-one recommendations. It recommended that schools should be jointly supported by state grants and rate grants depending on the degree of knowledge attained by the children during the year preceding the payment of the grant. The schools would have to show eight square feet of superficial area for each child in average daily attendance. Special state grants were to be offered to schools with less than sixty pupils. The combined grants were not to exceed the fees and voluntary subscriptions combined, with an additional grant to stimulate regular attendance. The system was to be carried out by partly elected and partly co-opted County and Borough Boards of Education. Ministers of religion were also to sit on these bodies. The proposals of the commissioners were totally inadequate to meet the educational position, which was attacked in a different way, first by the Revised Code introduced by Mr. Lowe (*q.v.*) in 1861, next by Select Committees in 1865 and 1866, and finally by the statutory system of compulsory school attendance introduced in 1870 and 1876. In 1886 a Royal Commission, the Cross Commission, was appointed to inquire into the working of the Elementary Education Acts. It reported at great length in 1888 with a minority report by eight out of the twenty-three commissioners. Its recommendations as to raising school age, the development of evening schools, special help for rural schools, and the creation of undenominational training colleges have been largely carried out.

In 1861 a Royal Commission, the Public Schools, or Clarendon, Commission, was appointed to inquire into the nine leading public schools of the country (Eton, Winchester, Westminster, Charterhouse, Harrow, Rugby, Shrewsbury, — all boarding schools, St. Paul's and Merchant Taylors, day schools) which were then educating 2696 boys. The commissioners also dealt with Marlborough, Cheltenham, Wellington (boarding schools)

and the City of London and King's College Schools, London, (day schools.) The commissioners reported in 1864, and in 1868 the Public Schools Act was passed. In 1864 another Commission, Schools Inquiry or Taunton Commission, dealt with the endowed schools and problems in secondary education not considered by the Duke of Newcastle's Commission of 1858 and the Clarendon Commission of 1861. The Schools Inquiry Commission included Frederick Temple, William E. Forster, Dean Hooke, and Sir Stafford Northcote, assisted by James Bryce, Matthew Arnold, and Joshua Fitch. Its report, issued in 1867, is of the greatest value in the history of English secondary education and contained a number of important suggestions for the improvement of the educational and administrative systems which were not adopted until the end of the century. This commission reported and stated that there were 572 endowed grammar schools at work with a net income of £183,016 and exhibitions to the annual value of £13,897. It was for this Endowed Schools Commission that Matthew Arnold reported in France, Germany, Switzerland, and Italy and advised the country to "organize your secondary and your superior instruction." The commission specially dealt with secondary education for girls. Their report led to the passing of the Endowed Schools Act, 1869 (*q.v.*), and the rapid multiplication of secondary schools for girls as well as boys created out of the old endowments. Under this Act, Endowment Schools Commissioners were appointed who before their powers passed to the Charity Commissioners in 1874 reformed and gave schemes to no less than 235 schools. The working of the Endowed Schools Acts was subjected to Parliamentary inquiry from 1884 onwards. In 1881 a Committee of the Education Department was appointed by the Government to inquire into the conditions of intermediate and higher education in Wales. This led to the Welsh Intermediate Act of 1889 and finally to the creation of a Welsh Department working in connection with, but independent of, the English Board of Education. In 1894 a Royal Commission, the Bryce Commission, was appointed "to consider what are the best methods of establishing a well-organized system of secondary education in England, taking into account existing deficiencies, and having regard to such local sources of revenue from endowment or otherwise as are available or may be made available for this purpose." The Rt. Hon. J. Bryce was chairman, and three of the seventeen commissioners were ladies. The Report in nine volumes, presented in August, 1895, recommended the appointment of a general Education Department under a Minister of Education and a Consultative Education Committee (one third appointed by the Crown, one third by the Universities, and one third coöpted), which should absorb the Charity

Commissioners (as regards education), the Science and Art Department, and the Education Department. The creation of the Board of Education by an Act of 1899 in part carried these proposals into effect, while the Education Act, 1902, provided for the local organization of education to some extent on the lines suggested by the Royal Commission.

In 1901 an interdepartmental committee of the Board of Education and the Local Government Board reported on the whole question of the employment of children out of school hours. The practice was not altogether condemned. Legislation has followed. (See CHILDHOOD, LEGISLATION FOR THE CONSERVATION AND PROTECTION OF; CHILD LABOR.)

PAROCHIAL SCHOOLS. — See PARISH SCHOOLS

PAROXYSM — A sudden attack and sometimes only an exacerbation of certain diseases. The term is also commonly used to indicate a spasm effect, *e.g.*, paroxysms of fear. See EPILEPSY; SPASM S. I. F.

PARSONS COLLEGE, FAIRFIELD, IA — A coeducational institution founded by Lewis B. Parsons of Buffalo, N.Y., who, in 1855, bequeathed the residue of his estate, amounting to \$37,000, for the purpose of "endowing an institution of learning in the State of Iowa." In 1874 the citizens of Fairfield, cooperating with the Presbyterian Synod of Iowa, organized to secure the bequest, donating \$30,000. The charter was received Feb. 24, 1875. Newly elected trustees are subject to confirmation by the Synod of Iowa. Sixteen members of the board and the president of the institution must be members of the Presbyterian church.

Buildings and equipment are valued at \$220,000. The productive endowment is \$229,000. The annual income from tuition and invested funds is \$20,000. There are sixteen members of the teaching staff, eight of whom are professors. There are about 100 students in the College proper. The Academy maintains a four-year course under a separate teaching staff. The B.A., B.Ph., and B.S. degrees are granted. Advanced degrees are not granted. H. M. G.

PART-TIME ATTENDANCE AT SCHOOL. — **England and Wales.** — The system of part-time attendance or the half-time system has

PART-TIME ATTENDANCE

been particularly prevalent in England and Wales. A half-timer or partial exemption scholar is defined by the Board of Education as one "who is certified by or on behalf of the Local Education Authority to be qualified by age and attainments or previous attendance for employment in conformity with the by-laws." The problem of the half-timer is thus part of the greater problem of child labor (*q.v.*) which includes not only street trading and casual employment, but also the regular employment of school children out of school hours.

The half-time system arose with the factory and educational legislation which followed the industrial revolution. Its beginnings are found in the educational clauses of the Factory Acts of 1833 and 1844, which required children employed in factories to attend school half the day or so many days per week, but it was the Education Act of 1870 that firmly established the system. Under this Act was granted partial relief from compulsory attendance at school to children between the ages of ten and thirteen who had reached a certain standard of education. Although subsequent Education Acts (1876, 1880, 1893, 1899) have modified the conditions for exemption, the system of to-day is practically the same as that of 1870. Exemption may still be obtained by passing a "labor examination" varying in difficulty from that of Grade III to that of Grade VI, while since 1899, 300 attendances (morning or afternoon sessions) for each of five preceding years, not necessarily consecutive, have also sufficed. The qualification is, in many cases, absurdly low and is further complicated by the fact of local option. A city or county council may or may not pass by-laws permitting half time within its jurisdiction. Some cities, *e.g.* London, Birmingham, Plymouth, and Newcastle, have no half-timers; other towns, especially the textile towns of the North, have large numbers consequent upon low standards for exemption. Four half-timers out of every five are found in the factory districts of Lancashire and Yorkshire.

The following table shows the development of the half-time system. The figures, however, must be interpreted cautiously, because they represent the total numbers in any given year. The actual number at any given moment was, of course, much smaller. Thus in 1906-1907 the average number of half-timers was only 47,360, although the total for the year was 82,493.

YEAR	NO OF HALF-TIMERS
1875-1876	201,294
1890-1891	173,040
1895-1896	119,747
1900-1901	74,498
1905-1906	81,981
1909-1910	75,758
1910-1911	71,475

The lowest number, previous to 1910-1911, was reached in 1900-1901. The upward turn

PART-TIME ATTENDANCE

taken at this time was due to the Act of 1899, which introduced the principle of exemption for attendance only.

The half-timer introduces many problems into school organization and administration. He is difficult to fit in with other children because he receives only one half the lessons. Lessons must either be duplicated for him, thus causing his classmates to mark time, or he must be neglected and allowed to fall hopelessly behind them. Attempts to segregate him have also proved futile. There are also certain moral and physical dangers connected with his employment. He learns "mannish" ways without developing manly control, with the result that he tends to become a nuisance in the home, the school, and the street. The strenuousness of modern industrial life also leaves its mark upon him; all the physical measurements that have been made show him to be the inferior of his school fellows in height and weight.

Yet many arguments are given in support of the system. It is said that the half-timer receives a good technical training in the workshop, that the requisite dexterity of fingers can only be gained at the early age of twelve or thirteen, that it is good to develop a spirit of independence, and so forth. On the other hand, it is pointed out that instruction is given in a haphazard fashion by any operative who happens to be his master or mistress for the time being, that the finger dexterity can be acquired equally well at fifteen or sixteen, that the wages earned (\$.30 to \$1 a week) are seldom of absolute necessity to a family, and that the employment kills off any desire on the part of the half-timer to continue his education at evening or technical classes. It must be acknowledged, however, that the system is extremely popular with the half-timers themselves. They, as wage earners, enjoy more independence and liberty at home, and they have a certain amount of pocket money to spend.

The system, which is opposed by the best elements in English life, is continued mainly by the inertia of custom, but is also fostered by the greed of non-thinking parents. An Interdepartmental Committee formed to inquire into the question of Partial Exemption from School Attendance reported, in 1909, in favor of its abolition. Although the government has never taken upon itself to end the system, it supported the bill of Mr. Walter Rea, February, 1912, which proposed to raise the age of exemption from twelve to thirteen and to refuse exemption to all children who are not beneficially employed. The bill has passed its second reading by a large majority (April, 1912) and, if facilities are given by the government, it should become law on Jan. 1, 1913.

P. S.

In the United States the part-time system exists only in a few cities, and there as

PARTRIDGE

a result of inadequate seating facilities. As these conditions are merely exigencies of rapidly growing communities, the system of part-time attendance has no significance. See NEW YORK CITY.

PARTIALITY.—See SCHOOL MANAGEMENT.

PARTRIDGE, ALDEN (1785–1854).—Founder of military schools in the United States; graduated from the United States Military Academy in 1806, and for twelve years an instructor in that institution. For two years he had charge of the exploration of the northwestern boundary of the United States. He organized several secondary schools upon military principles, after the pattern of West Point, for boys not amenable to the milder discipline of the ordinary schools. One of the most important of the military schools that he organized was that at Norwich, Conn. (1820), which was incorporated as Norwich University in 1834. His publications include *Lectures on Education* (1825) and many papers on military subjects. W. S. M.

See MILITARY EDUCATION.

PASCAL, BALISE.—See PORT ROYALISTS.

PASCAL, JACQUELINE (1625–1661).—French educator, younger sister of Blaise Pascal. While still in her early twenties, she tried in vain to persuade her father to allow her to enter a convent. After his death (1651), she became a nun, and was made submistress (1655) of the novices at Port-Royal (*q.v.*). In this capacity she was directly in charge of the education of the younger children, where she followed the method of training for which her brother was responsible, and she is deserving of no small portion of the credit for the success attained in this work with the younger classes. She stoutly resisted giving her assent to the Papal Bull against Jansenism, but in the end she was forced to yield and died of grief a few months later. Her most important writing was *Règlement pour les Enfants de Port-Royal* (1665). F. E. F.

PASCAL'S TRIANGLE.—A triangular array of numbers known long before the time of Pascal (*q.v.*), but so extensively studied by him as to be called by his name. The numbers are written in this form:—

1						
1	1					
1	2	1				
1	3	3	1			
1	4	6	4	1		
1	5	10	10	5	1	

and so on. Each number is derived by adding the number just above to the number at the left of the latter. The successive lines are evidently the coefficients of the various powers of a binomial, and the device has, therefore, considerable interest in the teaching of the binomial theorem. The triangle, or its substantial equivalent, first appeared in print on the title-page of a work by Apianus (or Bienewitz, 1495–1552), which appeared in 1527. The following is a facsimile of this first printed form

D. E. S.

PASSION.—This term is used to designate strong or uncontrolled emotional states. From the point of view of education such uncontrolled states of emotion are significant as indicating a lack of training on the part of the individual. Children, especially those who are more or less abnormal, are likely to exhibit fits of passion such as anger or rage. The corrective for such uncontrolled expressions of emotion is very commonly some general treatment of the whole physical system. A sharp distinction should be drawn between such emotional states and voluntary activity. The whole matter may be referred to the general discussions of emotions. C. H. J.

PASSOW, FRANZ (1786–1833).—German philologist, was born at Ludwigslust, Mecklenburg, and studied at the University of Leipzig under Gottfried Hermann. In 1807, although not quite twenty-one years old, he was appointed professor of Greek literature at the gymnasium of Weimar. He owed this appointment to Goethe, who had met the young man and had been very favorably impressed

by his enthusiasm for literature and classical antiquity. In 1810 he was called to direct the *Conradinum*, an educational institution in Jenkau, near Danzig. In 1815 he became professor of philology and archaeology at the University of Breslau, where he remained until his death. In 1818 he became involved in the controversy which raged around the instruction in gymnastics introduced by Harnisch (*q.v.*). Passow, who was fond of physical exercise, strongly supported Harnisch, and published in his defense a book called *Turnziel (Aim of Gymnastics)*, which nearly cost him his position. Attempts were made to remove him from Breslau, but his reputation as a scholar and teacher was too great. His chief work is his great lexicon of the Greek language (*Handwörterbuch der griechischen Sprache*), first published in 1819; a recent edition appeared in 1901. F. M.

PATON, JOHN BROWN, D D (1830–1911). — Was born at Galston in Ayrshire. After attending the parish school he acted as usher in a private school in Gloucester, entered Springhill Congregational College with R. W. Dale, took his M.A. at London University with Gold Medal for Philosophy; became minister of the Wicker Church, Sheffield. In 1863 he was appointed first principal of the Congregational Institute at Nottingham, founded to provide training for pastors and evangelists of country churches. He felt the social influence of the church and throughout his life advocated the coöperation of all Christian churches in the "Inner Mission" for the healing of social evils and preached redemptive service. In 1870 and the following years he stood out against the policy of secularism in the public elementary schools under the new Act. He coöperated with Professor James Stuart in the early years of the University Extension Movement (*q.v.*), and the University Lectures at Nottingham led to the foundation of the University College (1881). Seeing the need of public education between the ages of thirteen and seventeen and the inadequacy of the old night school to supply the need, he started classes under the Nottingham School Board which combined recreative subjects with

musical drill, stereopticon lectures, and practical handwork of all kinds. This led to the foundation of the Recreative Evening School Association (1885), which largely increased the numbers in continuation schools and paved the way for a new development of evening classes leading to higher technical and artistic education. Taking a hint from the Chautauqua Association (*q.v.*), he founded the National Home Reading Union (*q.v.*) (1889), which gives guidance and help for reading, private and associative. In connection with the Home Reading Union the first summer meeting in England was held at Blackpool, leading to the regular extension meetings at Oxford and Cambridge. He founded the Coöperative Holidays Association (*q.v.*) to provide cheap holidays in which working folk should have the companionship of university men and women. He founded at Longfield a Colony of Mercy (1895) on the model of Bodelschwing's Colony at Bielefeld for the practical training of unemployed and the educational care of epileptic and feeble-minded children, hitherto herded together with the imbeciles in the workhouses. He founded the Social Institute Union (1886) with a view to providing, for the most part in the Board School buildings, counter-attractions to the public house. He founded the Boys' Life Brigade, with objects and methods similar to the Boys' Brigade, but dispensing with all use of guns, and laying stress on ambulance work, fire drill, and all training for the saving of life. He also founded the Girls' Life Brigade and the Brigades of Service for young men and women. He was one of the moving spirits in the formation of the British Institute for Social Service (1904), the Christian Union for Social Service (1894), and the Scottish Christian Social Union (1901). He was chairman of a Vagrant Children's Protection Committee. He was much interested in the reestablishment of the yeomanry on the land and founded a Cooperative Small Holders' Association and a Coöperative Banks Association. He was instrumental in adapting the Elberfeld systems of poor relief to English conditions and in the establishment of Civic Guilds of Help in large towns of England. He was joint editor of the *Eclectic Review* (1858 to 1861) and of the *Contemporary Review* (1882 to 1888).

In addition to numerous pamphlets he wrote: *A Review of Renan's Life of Christ; The Origin of the Priesthood; The Twofold Alternative, Materialism or Religion and the Church, a Priesthood or a Brotherhood; The Inner Mission of the Church*; two volumes of Collected Essays: *Church Questions of To-day and the Apostolic Faith and its Records*. J. L. P.

PATRICK, ST.—See IRELAND, EDUCATION IN.

PATRIOTISM.—The feeling which moves the individual to identify with his own the interests of the social group to which he belongs, and to speak and act accordingly.

Origin and Development of Patriotism.—Sociology ascribes the origin of patriotism to the family life, the family being the earliest of the social groups. In primitive life support, protection, and authority were chiefly represented by the father; hence loyalty to the father was both natural and necessary. Fatherism was therefore the earliest form of patriotism. With the enlargement of the family into the clan, gens, and tribe, the interests of particular families were merged in the interests of the group of which they were component elements, and loyalty to the family passed over into clannishness or tribalism. With the amalgamation of tribes into states and nations patriotism enlarged into love of country, its most conspicuous form to-day.

Patriotism, then, originates in association, and association is the condition of its development. From this fact we may infer that, if political and social organization and amalgamation continue, patriotism will undergo a consequent transformation. A "Parliament of man and Federation of the world" would as certainly conduce to cosmopolitanism or political humanism as tribal association has produced tribalism, and the consolidation of states into nations has produced modern patriotism. Love of country would naturally give place to love of kind.

Instinctive Patriotism.—Patriotism, as here defined, is primarily a sentiment or feeling. This feeling is instinctive. Patriotism in which feeling is the predominant element may thus be called instinctive patriotism. Now it is characteristic of an instinct that it acts without reflection. Though originally purposive in action, and serving as an element in individual or group preservation, instinct takes no consideration of objective circumstances. It is blind impulse. When the stimulus is provided, it operates; and its operation has often led in the course of biological and social evolution to the destruction both of individuals and of groups. Patriotism, therefore, so far as it is merely instinctive, is impulsive, blind, unreasoning, and irreflective. It thrills, it hurrahs, it boasts, it fights and dies without calmly considering either occasion or consequence. It resents a fancied national insult without stopping to ascertain whether it is real. It flies to the defense of the supposed interests of its group without inquiring whether the danger is actual. It is blind patriotism and springs from the emotional side of the mind. It differs in no essential respect from the instinct of the tiger to defend its

young, or from that of the wild cattle of the prairie to defend the herd. It is easily aroused and easily stampeded. It is a feeling for one's country uncontrolled by intelligence; zeal without knowledge. Under its promptings the patriotic is sometimes the idiotic. The utterances and actions sometimes evoked by it show that a man may be a patriot and still be a fool.

Obviously great national and social dangers may arise from manifestations of instinctive patriotism. As antipathy toward other nations, and consequent irreflective action, it provokes suspicion, jealousy, hatred, and unnecessary war. It inspires irresponsible and mischievous declarations with respect to other people, and sneering comments upon their customs and peculiarities, which tend to provoke hatred and hostility. As Chauvinism and Jingoism it prevents that national receptiveness which is so essential to progress. It is not eager to learn from other nations for the very simple reason that it thinks they have nothing superior to teach. To the instinctive patriot nothing in foreign nations is worthy of emulation or adoption. He speaks without the slightest reverence of "Japs" and "Chinks" and "Dagoes"; of "Wild Irishmen" and "Flatheaded Dutchmen." Such a "patriot" may be a gentleman so far as his more intimate personal relationships are concerned, but as a national representative he is often a braggart or a bully. No matter, then, how patriotic one may be, if one's patriotism is merely instinctive it is irrational and irresponsible, and consequently a danger to one's country.

In spite of the dangers of instinctive patriotism, however, it must be recognized that, like other instincts, it has served, and may again serve, a very useful purpose. Indeed, in the absence of social intelligence, it has been essential to the preservation of social groups. When, for instance, the life of a nation is in danger its citizens must rise instantly to its defense. There is no time for serious reflection. To deliberate is to be lost. Hence the social impulse of resentment and the disposition to spring to arms is an element of national survival, for it leads the citizens to act in concert and so more effectively. Without instinctive patriotism no group in a hostile environment could have survived. On the whole, those groups in which it was most highly developed are the ones which have persisted. Instinctive patriotism, then, has unquestionably been an element in social survival as well as in social danger and destruction. But, however serviceable it may have been in the past, or however necessary now in a critical national emergency, it is not the kind of patriotism which is most needed to-day. It involves governments in needless strife, and it renders citizens easily susceptible to the pernicious influence

of kings, diplomats, and unscrupulous politicians. It should, therefore, be supplanted as rapidly as possible by the patriotism of intelligence.

Intelligent Patriotism.—It is the function and power of the intellect to inhibit, sometimes to eliminate, an instinct. Even the instinct of self-preservation, strong as it is, has sometimes been wholly inhibited by a duly informed and reflective mind. The proper intelligence may therefore modify, even reverse, the actions springing from instinctive feeling. Patriotic sentiment may be held subject to a thorough knowledge of political and social conditions and a sense of justice. When so held it becomes intelligent patriotism. Intelligent patriotism, then, is patriotic feeling, instinctive patriotism, under the control and guidance of knowledge and reflection. It is love of country and the disposition to serve it, coupled with a knowledge of how to serve it well. It does not yield to impulse, but controls it. It looks before and after. It restrains a nation from fighting when there are no real interests at stake. The difference between the two kinds of patriotism is practically the difference between impulsive action and reasoned action.

The Teaching of Patriotism.—With this distinction between the two kinds of patriotism it ought to be clear that in the effort to develop patriotism by means of education, emphasis should be laid not upon stimulating patriotic emotion, but upon increasing the factor of intelligence. As a rule, we may safely rely on the existence of patriotic feeling and devote attention almost, if not quite, exclusively to the promotion of knowledge appropriate to its control. Saluting the flag, the singing of patriotic songs, Fourth of July celebrations as usually conducted, to say nothing of the patriotic appeals from pulpit and rostrum, are directed primarily to stimulating the patriotic instinct. Emotional effects are thereby easily produced. Those who practice these methods really believe that they are developing patriotism, but they are merely inciting patriotic emotion without giving it the proper means of guidance. The really needed and difficult thing is to form the instinct of patriotism so that it will operate, even under trying circumstances, to the real advantage and safety of the nation. Education should result in imparting such knowledge of social history, civics, and ethics as will result in arousing a sympathetic interest in the merits and worthy achievements of all nations and races, a just pride in our own, and in the development of such habits of thought as will make patriotism, love of country, identical with loyalty and devotion to liberty, justice, and truth.

PATRIZZI, FRANCESCO.—See RENAISSANCE AND EDUCATION.

PAULSEN, FRIEDRICH.—Born July 16, 1846, in Langenhorn, Holstein, and died in Steglitz, near Berlin, August 14, 1908. He attended the *Volksschule* of his native village, and was prepared by Pastor Thomsen for the gymnasium at Altona, a higher class of which he entered in 1863. After receiving the *Reifezeugniss* in 1866 he began the study of theology at the University of Erlangen in accordance with the wishes of his mother; but he was unable to throw himself into the work with any enthusiasm, and therefore changed to philosophy, taking also classical philology and history, with a view to the possibility of becoming a gymnasial teacher. From 1867 to 1870 he was a student at Berlin (under Trendelenburg, Harms, and Bonitz); and also at Bonn and Kiel. After receiving his degree in 1870, Paulsen spent the next five years at the University of Berlin, partly in rounding out his knowledge, devoting himself particularly to the study of experimental physics, chemistry, anthropology, economics, jurisprudence, and politics, partly in composing his *Habilitationschrift*, *Versuch einer Entwicklungsgeschichte der Kantischen Erkenntnistheorie*. From 1875 to 1878 he served as a private docent at Berlin, from 1878 to 1894 as extraordinary professor, and from 1894 to his death as ordinary professor of philosophy and pedagogy. It was his aim, as he himself declared, to bring philosophy into vital relation with the general culture of the day, regarding it as an indispensable element of our social life. He did not care to make converts to a system; he was opposed to all partisanship and faction. The mission of philosophy was according to him not to coerce men's thought but to set it free, to train them in independent thinking, not to make them passive recipients of philosophies. Towards the close of his life he appealed to larger circles of the German public through the spoken and written word; "whenever a question became a burning issue," as Professor Kaftan said, "a word was expected from him to help clear the air."

In the movement for the reformation of secondary education in Prussia, Paulsen took a leading part. He was opposed to the Order of Studies, dating back to Johannes Schulze, which made the classical gymnasium the normal and only type of secondary schools and the

sole entrance gate to the various departments of the university, and insisted that the gymnasium, the realgymnasium, and the oberrealschule be placed on an equal footing. His recommendations, which had been ignored at the celebrated December Conference of 1890, were followed at the June Conference of 1900; the monopoly of the classical gymnasium was abolished. Paulsen also advocated freer methods of instruction in the upper forms, methods that would give greater scope to voluntary and spontaneous activity. "What Germany wants," he held, "is the Anglo-American college, which forms a very valuable transition stage between school discipline and the full freedom of German university life." Among his many valuable contributions to the literature of education, we mention the following books: *Geschichte des Gelehrtenunterrichts auf den deutschen Schulen und Universitäten* (2 vols., 1885 and 1896); *Das Realgymnasium und die humanistische Bildung* (1889); *Die deutschen Universitäten und das Universitätsstudium* (1902, trans. by Thilly and Elwang); *Das deutsche Bildungswesen* (1906, trans. by Lorenz); *Moderne Erziehung und geschlechtliche Sittlichkeit* (1908); *Richtlinien der jüngsten Bewegung im höheren Schulwesen Deutschlands* (1908); *Pädagogik* (ed. by Kabitz, 1911).

Paulsen's metaphysics, which shows the influence of Spinoza, Fehner, Lotze, Schopenhauer, and Kantian criticism, is a system of idealistic monism, panpsychism, and pantheism; the physical processes and the psychical processes are one and the same reality, perceived in different ways, the former through the mediation of the senses, the latter directly, as they are in themselves, in consciousness. In the physical sphere everything is mechanically conditioned, as natural science teaches; but the mental realm, which is the true reality, is a world of purposive activity. The material world is the outward expression of a universal consciousness, to which the individual consciousness, stands in the same relation as the particular human body to the universal system of bodies. This conception of the universe is set forth in the *Einleitung in die Philosophie* (1892, trans. by Thilly), a book which has passed through twenty-three editions. Paulsen's moral philosophy, as presented in his *System der Ethik mit einem Umriss der Staats- und Gesellschaftslehre* (1889, eighth ed., 1906, trans. by Thilly), has been characterized by him as teleological energism to distinguish it (1) from Kantian intuitionism and (2) from English utilitarianism. The end of the will is not feeling but action; the highest good is an objective content of life, consisting in the perfect exercise of all human mental powers, in which pleasure forms a part. The end or purpose realized by morality is grounded in the human will, is something toward which the will is essentially directed. In a later

account, *Kultur der Gegenwart: Systematische Philosophie* (pp. 289 ff.), what was formerly called the individual's basal will is spoken of as the objective will; the system of objective morality is regarded as the product and function of a universal reason immanent in the social forms of historical life. He also wrote *Immanuel Kant: Sein Leben und seine Lehre* (1898, trans. by Creighton and Lefevre), and collected many essays in *Gesammelte Vorträge und Aufsätze* (2 vols., 1906). F. T.

PAVIA, UNIVERSITY OF.—See ITALY, EDUCATION IN

PAYMENT BY RESULTS.—A system of apportioning public money for education based on the results of examinations. Payment by results was introduced into England by the Revised Code, issued May 9, 1862, and continued with modifications until 1897. Robert Lowe (*q v*) was responsible for its introduction. As originally introduced the grants were payable upon the results of individual examinations of pupils in Standards I to VI, in the three R's, and plain needlework for girls. Certain other conditions were also imposed, e.g. number of attendances, adequacy of buildings, qualifications of teachers, etc. The grants were paid to the managers of schools and not directly to the teachers. The curriculum thus depended on the distribution of grants, and subjects were added or removed according to their grant-earning capacity. At first everything beyond the three R's was discouraged. In 1867 grants were given for geography, grammar, and history as "specific subjects." In 1871 there were added as "specific subjects" algebra, geometry, natural philosophy, physical geography, natural science, political economy, and languages (English literature, and elements of Latin, French, and German). Vocal music was encouraged in a similar way a year or two later. In 1878 geography, history, grammar, and plain needlework became class subjects, and grants were given on class, not individual, examinations. The "specific subjects" in this year were mathematics (algebra, Euclid, and mensuration), Latin, French, German, mechanics, animal physiology, physical geography, botany, domestic economy (for girls). In 1882 the

Seventh Standard was recognized for purposes of the examination, and English literature and grammar, physical geography, and elementary science and history for the three highest standards became class subjects. Practical training for girls was also encouraged. In 1890 history was extended to all classes, drawing was made compulsory for boys, manual training and housewifery were counted as attendance subjects, shorthand became a "specific subject," and laundry work a "special." In 1891 navigation, in 1892 horticulture, in 1893 dairy making, in 1894 domestic economy and hygiene, became "specific subjects." In 1895 payment by results in elementary subjects was abolished for older schools, and in 1897 payment for "specific subjects" also disappeared.

Payment by results perhaps more than any other cause retarded the development of elementary education in England. Its only merits were that it established standards at a time when all teachers were not trained, artificially affected the curriculum, and was cheap. It was also a step in advance in so far as teachers were compelled to pay as much attention to lower classes as to higher, and to backward as well as to bright pupils. The latter, however, too often were reduced to the level of their inferiors. But while it introduced uniformity, there followed dull, mechanical methods and all other abuses connected with an exaggerated system of examinations. The recovery from the system is slow but certain; initiative and adaptation to local needs are being more and more encouraged; and mass education is being replaced by individual care and attention.

The system of payment by results is still employed by the Intermediate Board in making appropriations for secondary education in Ireland. The system is, however, being gradually modified by the introduction of inspection, and the imposition of certain conditions relative to the school buildings. (See IRELAND, EDUCATION IN.) In the Province of Victoria, Australia, the system was abolished as recently as 1906.

PAYMENT OF TEACHERS.—See TEACHERS' SALARIES.

PAYNE, JOSEPH (1808-1876).—English educator, born at Bury St. Edmund's.

His education was but scanty, and he only attended school for a short time when near the age of fourteen. Although compelled to earn a livelihood at an early age, he applied himself with great industry to the study of the classical and English literature. In 1828 he became assistant in a London school and about this time came across Jacotot's (*q.v.*) work. His pamphlet, *A Compendium Exposition of Professor Jacotot's celebrated System of Education* (1830), brought him to the notice of Mrs. David Fletcher, who made him tutor to her children. By associating other children with them Payne was soon able to open the Denmark Hill Grammar School. In 1837 he married Miss Dyer, who herself kept and continued to keep a girls' school. In 1845 he moved to Leatherhead and opened the Mansion House School, one of the best private schools of the time. Retiring from this work in 1863, Payne devoted himself to the advancement of the cause of education. He supported the Women's Education Union and the Girls' Public Day School Company (*q.v.*), which sprang from it. He took a keen interest in the Froebelian theories and the kindergarten movement, and studied the work of Pestalozzi and of Jacotot. Of the last named he was the chief exponent in England. He was intimately associated with the College of Preceptors (*q.v.*), before which he frequently lectured on educational subjects. When in 1872 the College established a chair in the Science and Art of Education, then the first in England, Payne was appointed to it. In 1874 he made a tour for the purpose of investigating educational institutions in North Germany. Not only did Payne devote himself to the cause of education, he was a keen student of philology and wrote a paper on the *Norman Element in the Spoken and Written English of the Twelfth, Thirteenth, and Fourteenth Centuries* for the Philological Society, of whose council he was chairman in 1873-1874. (See EDUCATION, ACADEMIC STUDY OF.)

While he made no original contributions to educational thought, Payne was a pioneer in introducing and familiarizing English educators with the best theory and practice of his day. If he exaggerated the value of Jacotot's methods, it was done largely in a spirit of reaction against the mechanical work of the schools. Through his connection with the College of Preceptors, which introduced the first examinations for teachers in England at the suggestion of Payne and C. H. Lake, he was able to inspire a number of teachers with his own enthusiasm for educational study and progress. His chief educational writings have been edited first by R. H. Quick in one volume, and reedited, with the addition of a second volume, by his son, Dr. J. F. Payne. Volume I (1883) contains *Lectures on the Science and Art of Education*, and Volume II (1892), *Lectures on the History of Education, with a Visit*

to *German Schools*. The first volume includes a list of Payne's published works.

PAYNE, WILLIAM HAROLD (1836–1907).—University professor of education; born at Farmington, N.Y., the 12th of May, 1836. He was educated in the common schools and at the New York Conference Seminary. He began his teaching career in the public schools of New York. He was principal of schools at Three Rivers, Mich. (1858–1864); superintendent of schools at Niles, Mich. (1864–1866); principal of a seminary at Ypsilanti, Mich. (1866–1869), and superintendent of schools at Adrian, Mich. (1869–1879). His work as a school superintendent was distinguished by his untiring efforts to supplement the pedagogic training of the teachers under his charge. In 1879 he was called to the newly organized chair of the science and art of teaching at the University of Michigan, one of the earliest permanent university professorships of education. From 1888 to 1901 he was president of the University of Nashville; but upon the death of Professor B. A. Hinsdale he returned to his old post in the University of Michigan. His writings include *Chapters on School Supervision*, *Outlines of Educational Doctrine*, and *Contributions to the Science of Education*. Professor Payne was much interested in French educational thought, and he made excellent translations of some of the writings of Gabriel Compayré, including *The History of Pedagogy*, *Lectures on Pedagogy*, *Elements of Psychology*, and *Applied Psychology*. He also translated and edited Rousseau's *Emile*. For four years he was editor of the *Michigan Schoolmaster* (1866–1870). W. S. M.

See EDUCATION, ACADEMIC STUDY OF.

PEABODY, ANDREW PRESTON (1811–1893).—College professor; graduated at Harvard in 1826, after which he studied theology at the Cambridge Divinity School. He taught school for three years; was three years tutor at Harvard, and for twenty-seven years was engaged in the ministry. He was professor of Christian morals at Harvard from 1860 to 1881, and acting president of the college in 1862 and again in 1868–1869. His publications include *Sermons for Children* (1866), *Manual of Moral Philosophy* (1874), and *Harvard Reminiscences* (1888). He also published a Sunday School hymn book. W. S. M.

PEABODY EDUCATION FUND.—One of the great educational foundations which have contributed to the remaking of Southern education. In 1867 George Peabody (q.v.) gave \$3,000,000 in trust for the promotion of education in the South. Through various

causes this sum shrank for a time to \$2,000,000. Peabody is said to have relied largely on the advice of Robert C. Winthrop in the disposal of the fund and in the arrangements for carrying out its purposes. The conditions of the trust were so liberal and elastic that the trustees have been able to employ the fund in such a way as to educate the people of the South to certain needs, which when realized they must themselves satisfy. Thus the fund has established standards along different lines. The money has been used for the following purposes: (1) Aiding and establishing public schools in the large towns and cities, and thus practically beginning and supporting systems of public education until taken over by the local authorities. (2) Similarly assisting the rise of state systems, a task almost completed by 1875. (3) Encouraging the professional training of teachers by the establishment of a normal school at Nashville (Peabody Normal College, 1875) and granting scholarships to students of ability. This led to the general establishment of normal schools and by 1903 the trustees were again free to dispose of their fund in another direction. (4) Establishing an institution for the higher professional education of teachers. This decision was prompted by a movement begun in 1902 by President Porter of the Normal College, the faculty and alumni, and the citizens of Nashville. The Peabody Board recognized the value of the plan in 1903 and decided upon its adoption. The result is the George Peabody College for Teachers, which has received an endowment of \$1,000,000 from the fund, land and buildings, valued at not over \$250,000, from the University of Nashville, with which it was associated for thirty-six years, and grants from the State of Tennessee (\$250,000), the county of Davidson (\$100,000), and the city of Nashville (\$200,000). The Trustees of the Fund have also offered to set aside \$500,000 additional for the endowment of the College, provided a further sum of \$1,000,000 is raised before Nov. 1, 1913. The College, to be opened in 1913, promises to be of the highest service to the educational Renaissance of the South. The new president is Dr. Bruce R. Payne. (5) Promoting rural consolidation of schools and the advancement of rural education by making grants towards the salaries of supervisors in many of the states of the South.

The Board of Trustees consists of sixteen members, who have always been men of the highest distinction in all walks of life. The most active associates in the early days were Hon. R. C. Winthrop, Hon. Hamilton Fish, Bishop MacIlvaine, Dr. Barnas Sears, the first agent, Dr. J. L. M. Curry, the second agent, Dr. Eben Stearns, first president of the Peabody Normal College, and Dr. W. H. Payne, his successor. At the present time Mr. J. Pierpont Morgan, Hon. Joseph H.

Choate, and Hon. Theodore Roosevelt are members of the Board of Trustees. Professor Wickliffe Rose is the general agent.

PEABODY, ELIZABETH PALMER (1804-1894).—American apostle of Froebel and organizer of the first kindergartens (*q.v.*) in the United States; was born at Billerica, Mass. the 26th of May, 1804. Her mother, a gifted woman, conducted a private school, at which Elizabeth and her sisters Sophia (afterwards Mrs. Nathaniel Hawthorne) and Mary (afterwards Mrs. Horace Mann) were educated. At the age of eighteen years Miss Peabody began her career as a teacher in Boston. Later she was associated with A. Bronson Alcott (*q.v.*) in the famous Temple School. In connection with her teaching she contributed to many literary and educational journals, including the *Dial*, the *Christian Examiner*, the *Democratic Review*, and Barnard's *American Journal of Education*.

In 1859 she became acquainted with the educational ideas of Froebel, and the next year she opened a kindergarten in Boston—the first in America. In 1867 she went to Europe to study kindergarten principles and practices at first hand, and through her influence Emma Marwedel (*q.v.*) and several other experienced German kindergartners were induced to come to America. The normal classes which she conducted in Boston trained most of the early prominent American kindergartners (including Miss Lucy Wheelock). From 1873 to 1877 Miss Peabody edited the *Kindergarten Messenger*, and in 1877 the American Froebel Union, of which she was the first president, was formed.

Her publications include *Hebrew History*, *Grecian History*, *First Steps in History*, *Chronological History of the United States*, *Record of a School* (an account of Mr. Alcott's Temple School), *The Kindergarten*, *Education in the Home*, *the Kindergarten*, and *the Primary School*, *Guide to the Kindergarten and Moral Culture of Infancy* (with her sister Mrs. Horace Mann), *Lectures in the Training Schools for Kindergartners*, *Kindergartens in Italy*, and a translation of *De Gerando's Moral Self-Education*. She also contributed several papers to Henry Barnard's comprehensive volume *Kindergarten and Child Culture*. Miss Peabody was interested not only in the kindergarten, but in all phases of educational work, including the education of the American Indian. She died at Boston the 5th of January, 1894.

PEABODY, GEORGE (1795-1869).—Benefactor of education and founder of the Peabody (Educational) Fund (*q.v.*); was educated in the common schools of Danvers (now Peabody), Mass. He engaged in business and made a fortune which he gave to various educational institutions and agencies. He founded the Peabody Institutes at Danvers, Salem, and Baltimore, and made large bequests to Harvard, Yale, and Kenyon Colleges. One of his largest bequests was to the Peabody Fund (*q.v.*) in 1867, "for the encouragement and promotion of intellectual, moral, and industrial education among the young of the more destitute portions of the Southern and Western states of the Union." One of his biographers says of him, "In the greatness of his benevolence George Peabody stands alone in history."

PEABODY, SELIM HOBART (1829-1903).—University president; was educated at the universities of Vermont and Iowa. He was principal of high schools at Burlington, Vt., Fond-du-lac, Wis., and Chicago; superintendent of schools at Racine, Wis.; professor in polytechnic colleges in Pennsylvania and Illinois, and president of the University of Illinois from 1880 to 1891. He was director of the educational exhibits at the World's Columbian Exposition at Chicago in 1893. His publications include *Astronomy* (1869), *Juvenile Natural History* (1869), *New Practical Arithmetic* (1872), and numerous articles in educational journals and the proceedings of educational associations.

W. S. M.

PEACE, EDUCATIONAL ASPECTS OF INTERNATIONAL.

—The peace movement is a part of the educational progress of the world. Whether in respect to its intellectual, economic, or moral phases, changes in opinion and practice have been effected by the educative process. Among the champions of the peace movement were Hugo Grotius, Jean Jacques Rousseau, and Immanuel Kant, and later, Noah Worcester, Elihu Burritt, Horace Mann, Professor Amasa Walker, and Edward Everett Hale, all of whom appreciated the necessity of educational propaganda.

The unification and direction of the intellectual life of the world through universities, colleges, and schools, has helped to prepare the way for international good will. The ease and rapidity of travel and communication by means of steam and electricity have helped to the

same end. The ever advancing tide of civilization with its various humanitarian movement has tended to sweep away many of the barriers which kept nations apart from each other. The grouping of men in international societies working in the fields of science, industry, and social reform, has led to a unification of the higher life and has promoted friendship among the leaders of progress. The labor organizations of the world have been active in promoting peace propaganda, and in national and international assemblies have declared themselves as opposed to proscription and in favor of arbitration. The process of persuading the nations to abandon the archaic method of settling difficulties by force and to adopt the modern method of the court of justice is now carried on not merely by pacifists, but by the clergy, the press, law associations, women's clubs, and even by bodies engaged in promoting the economic welfare of the community. A concrete example of this is seen in the *Report* (1910) of the Massachusetts Commission on the Cost of Living, which after a careful investigation finds that the great increase of expenditures for armament is the cause of enormous waste, affecting the common welfare of the people.

Among the organizations engaged in developing and organizing world sentiment for peace are six hundred and more peace societies, the oldest of which is the American Peace Society, whose Secretary is Dr. Benjamin F. Trueblood; the Interparliamentary Union, composed of representatives from the parliaments and congresses of the world, holding biennial meetings; the International Peace Congress, the eighteenth session of which was held in Stockholm in 1910; the national peace congresses, of which three have been held in the United States, namely, in New York in 1907, said to be the largest peace assembly ever convened, in Chicago in 1909, and in Baltimore in 1911; the Bureau of International Peace at Berne, Switzerland, which undertakes to gather and distribute information and act as a clearing house for all propagandist work; the Mohonk Arbitration Conference, which has been held for the past seventeen years under the patronage and hospitality of Mr. Albert K. Smiley, and like all the other organizations mentioned has been highly educative in its plan of work and successful in interesting the leading merchants, bankers, lawyers, clergymen, and publicists in the moral, social, and economic importance of the peace movement. Of the organizations which are intended to influence students in schools, colleges, and universities, there is the World Peace Foundation, for the support of which Mr. Edwin Ginn has set aside \$1,000,000, the income of which is to be applied in the publication of books and tracts on the history and progress of peace and in general propaganda work of an educative character. Closely affili-

ated with this Foundation is the American School Peace League, the object of which is to organize the teachers of the public schools in behalf of such teaching of history and other subjects and in such international exchange of teachers and correspondence as shall promote friendship among the youth of different lands. Through its influence the 18th of May, the anniversary of the calling of the first Hague Conference, is now celebrated largely throughout the United States as Peace Day. The Intercollegiate Peace Association has already organized oratorical contests in the colleges of several states. The Cosmopolitan Clubs, now forming a national association, afford meeting grounds in universities for men of different nations. Of the Harvard Cosmopolitan Club President Eliot has declared that it is the most interesting in the university. The Corda Frates, an international federation of students which has more than 15,000 members in European universities and has recently added 40,000 French secondary students, has as its principal object the promotion of the idea of solidarity and fraternity among students. The World Student Christian Federation, which includes five intercollegiate associations of America, Great Britain, Germany, and Scandinavia, with a membership of 138,000 students and professors, is increasingly influential as a factor for peace. The annual interchange of professorships initiated by the universities of Berlin, Harvard, and Columbia, and now extending to many other institutions, as well as the interchange of students, will tend to produce common interests in the field of scholarship and sound learning. The American Conciliation Society, under the chairmanship of Dr. Nicholas Murray Butler, publishes each month the best information available, using a mailing list of 70,000 names. The recent gift of eleven and a half million dollars from Mr. Andrew Carnegie is a crowning event in a remarkable series. The trustees of this endowment have already shown their purpose to make it serve educational ends by announcing that work is to be undertaken in three departments, namely, (1) international law, (2) economic aspects of peace, and (3) education and intercourse. The men already appointed to be at the head of the first two departments are distinguished as educators, and without doubt the remaining appointee will be of the same class. S. T. D.

PEACHAM, HENRY (? 1576-1643). — English author, born at Northmimms, Hertfordshire, the son of a country rector. He was educated at schools near St. Alban's and in London, and proceeding to Trinity College, Cambridge, graduated B.A. in 1594-1595 and M.A. in 1598. After teaching for a time at Wymondham in Norfolk he took up the literary profession, for which he was well enough equipped by a knowledge, in addition to letters, of botany, music, heraldry, mathematics, drawing, and painting. His first work was the *Graphice or the most auncient and excellent Art of Drawing with the Pen and Limning in Water Colours* (London, 1606) which passed through many editions as *The Gentleman's Exercise*. In 1613-1614 Peacham made excellent use of an opportunity to travel in France, Italy, and Holland as tutor to the sons of Thomas Howard, Earl of Arundel. It was during a stay at the country home of M. Ligny, a French scholar and soldier, that Peacham was struck by the limitations in the training of English gentlemen and was inspired to write the work by which he is best known, the *Compleat Gentleman* (1622). This work was addressed to William Howard, the eight-year-old son of Earl Arundel. The *Compleat Gentleman* is in the main a plea for the better education of the upper classes. The rest of the work is a series of chapters on the different studies, each of which gives an epitome of their content. Under the title, "Of Stile in speaking and writing, and of History," Peacham gives a list of authors to be read in Latin and Greek. The chapter on Poetry is of considerable interest, for Shakespeare, Ben Jonson, and others are omitted from the number of Elizabethan poets. One of the newer studies which was being introduced into England at this time is "Antiquities," including statues, inscriptions, and coins. In the chapter on "Drawing, Limning, and Painting" Peacham gives directions on color mixing and an account of the lives of eminent painters. Of special value in the education of a gentleman is the study of blazons, armory, arms, and the dignity of heralds. Under "exercise of the body" Peacham includes horsemanship, running, leaping, swimming, and shooting. Under the title of "Reputation and Carriage" are given the special qualities desirable in a gentleman: — temperance, moderation, frugality, thrift, and affable discourse to be cultivated with the help of anagrams, epigrams, and impressas. Of the function of travel in the education of a gentleman Peacham says, "In my opinion nothing rectifieth and confirmeth

more the judgment of a gentleman in forraigne affaires, teacheth him knowledge of himselfe, and setleth his affection more sure to his owne Country, than travaille doth." In deciding whether travel should be for pleasure or profit, Peacham pronounces emphatically for the latter, and he strongly recommends a sojourn in France for giving point to the accomplishments of the gentleman. The education of the gentleman is completed by a study of "Military observation," which deals with the different military ranks and gives a list of military commands. In a "much enlarged" edition, published in 1627, a chapter is added on fishing, "the honest and patient man's Recreation, or a Pastime for all men to Recreate themselves at vacant houres." Here an account is given of the Angle rod, lines, flats, baits, flies, and different kinds of fish. While the *Compleat Gentleman* nowhere gives a detailed description of the gentleman, it is a valuable contribution to our knowledge of what in theory at any rate was considered of value in his make-up. (See also GENTRY AND NOBLES, EDUCATION OF; MANNERS AND MORALS, EDUCATION IN.)

Peacham was unfortunately reduced to poverty in his old age and turned his pen to writing political and social pamphlets, of which the most interesting are: *The Art of Living in London, or a Caution how Gentlemen, Countrymen and Strangers, drawn by occasion of Businesse, should dispose of themselves in the Thriftest Way, not onely in the City, but in all other Populous Places* (1742), and *The Worth of a Penny, or a Caution to keep Money, with the Causes of the Scarcity and Misery of the Want thereof in these Hard and Merciless Times* (1641), a discussion of the economic condition of the country. Peacham is also said during this period to have written children's books at a penny each.

PEARSON, ELIPHALET (1752-1828). — First preceptor of Phillips Academy at Andover; graduated at Harvard College in 1773 and taught for five years at Andover. He was principal of the Phillips Academy at Andover from 1778 to 1786 and professor in Harvard College from 1786 to 1826, and acting president from 1804 to 1806. He was one of the founders of the American Education Society (*q.v.*) and was active in the American Academy of Science and Arts. He was the author of a Hebrew grammar and several papers on religious education. W. S. M.

PÉCAUT, FÉLIX (1828-1898). — French clergyman, author, and educator. He completed his studies at the Faculty of Protestant Theology at Montauban, and received an

appointment in his native city when only twenty-one years of age. Less than two years later he gave up his clerical calling on account of his heterodox views. These are set forth in his *Le Christ et la conscience* (1859). In the meantime he had moved to Paris, where he established a private school in conjunction with his friend Gaufres. His ideas on national education evolved during the years immediately following the disaster of 1870 appeared in a series of letters to the *Temps*, *Lettres de province*, and in *Études au jour le jour sur l'éducation nationale* (1871-1879). Jules Ferry (*q.v.*), then minister of public instruction, and M. Buisson, director of primary education, were responsible for appointing Pécaut to the staff of general inspectors. With the great increase in the number of departmental normal schools, it became more than ever necessary to provide for the recruitment of the teaching force for these training schools. Pécaut was selected to direct the girls' higher primary normal school at Fontenay-aux-Roses. He devoted himself heart and soul to the undertaking, and spent nearly all his remaining days in this, the most important work of his life, retiring in 1896. The school still reflects much of his spirit and devotion. See his *Deux mois de mission en Italie* (1880); *L'esprit de Fontenay* (1895); *Adieux à l'école* (1896); *L'éducation et la vie nationale* (1897); *Quinze ans d'éducation*, a posthumous publication of writings collected by his sons. PEDAGOGICAL SEMINARY. — See JOURNALISM, EDUCATIONAL.

PEDAGOGY. — Pedagogy is commonly understood to mean the science and art of teaching. The word is derived from the Greeks, among whom a pedagogue was the person, usually, if not always, a slave, who attended the young boy, going with him to and from school, carrying his materials for study, looking out for his wants and exercising authority over him. It is supposed that the pedagogues were often such slaves as would be useless for other tasks, and that they were not held in much respect even by the children who were placed in their charge. The name thus acquired in ancient times a connotation of lack of esteem, if not of contempt, which it has not entirely shaken off in modern usage.

A somewhat similar meaning became attached to the derived term, "pedagogy." Since the Renaissance educational reformers have drawn more and more attention to the significance of the process of education as contrasted with that of the subject matter taught. The study of this process has been for several centuries referred to as pedagogy. The philosopher Kant (*q.v.*) denominated his lectures on education as *Über Pädagogik*. They dealt especially with the formation of habit, and moral training and instruction. Thus defined, pedagogy concerned that aspect of education commonly held to be most childish and least interesting, a phase of life relegated to nurses, mothers, and pedagogues, and felt to have little in it to command the thoughtful attention of the strong in mind or will. In fact, the management and instruction of children was from the fathers' or schoolmasters' point of view thought to resolve itself into an authoritative display of superior power. Learning was treated as a matter of application on the part of the pupil. Application was regarded as a question of will, and will as to be governed by commands. But to command children was held, on account of their weakness and lack of resources, not to require great strength or to merit much thought or esteem.

But while, on account of its derivation from the word pedagogue and its application to an art held in little honor, the term pedagogy at first failed to carry the implication of a profound science, nevertheless the existence of the ideal of such a study and its resolute pursuit by a few reformers eventually gained for it a richer content and a higher standing. In the beginning its practical influence was felt especially in the elementary schools. The nineteenth century brought with it in the more advanced nations of the world an extraordinary expansion of the facilities for elementary education. The preparation of teachers for this work came to be in the hands of normal and training schools. These institutions devoted themselves largely to the pedagogy of the subjects taught in the common schools and to the problems of school management.

It came to be an accepted principle that elementary teachers should know not only the subjects they were to teach, but also the art of their craft.

Eventually the idea that the scientific study of education should not be confined to the problems of the elementary school led to the establishment of departments of pedagogy in colleges and universities. The University of the City of New York (now New York University) offered such courses in 1832. The same institution established a School of Pedagogy in 1890 and offered the degree of Master and Doctor of Pedagogy. The New York State Normal College at Albany gives the degree of Bachelor of Pedagogy. Many universities, especially in the western part of the United States created professorships in pedagogy in the last two decades of the nineteenth century. See EDUCATION, ACADEMIC STUDY OF.

The introduction of the study into higher education led to new difficulties in regard to the term pedagogy. It was felt to be essentially a normal school subject, concerned especially with the problems of the elementary school and "rule-of-thumb" methods of teaching the subjects of its curriculum. The specialists of the universities were prone to regard the power to teach as due primarily to knowledge of subject matter. In addition to this they admitted the importance of natural aptitude and of experience, but rejected the efficacy of methods. Many ridiculed outright the pretensions of "pedagogy," and resented its injection into the curriculum of higher education. Some even went so far as to criticize the entire influence of pedagogy on elementary education, on the ground that in its emphasis on interest it had demoralized the work of the school, giving us "soft" pedagogy.

Much of this criticism of pedagogy as a university subject had, doubtless, validity, and in consequence it was necessary to modify and expand its content in order to secure for it a permanent foothold and equality of rank. To mark the change there grew up a tendency to substitute the word *education for pedagogy* as a title for the department and for professorships. Thus the term "pedagogy" has to a considerable extent passed out of vogue. The newer "education" differs from the older "pedagogy" in two respects. First, it includes far more than method in teaching and school management; second, it is more scientific. Taking up the first point, we note that all the educational functions and agencies of society are considered; the history and administration of education are taken into account; the care of the body is brought before the attention as well as the care of the mind, and the education of defectives as well as of the normal child; the educational ideals and the curriculum are treated both in general and in detail and the relation of education to general

welfare is investigated. A good illustration of the expansion of the field is seen in the transition from the history of pedagogy such as we find in Compayré's volume with that title, to present-day history of education. Then the subject confined itself for the most part to the ideals and methods that have prevailed in the schools, together with some account of the conceptions and work of educational reformers. Now the historian of education tries to relate the processes and agencies of education to the institutional, economic, social, and cultural movements of history.

The second change that has come about with the transition from pedagogy to education lies in the more thoroughgoing and scientific methods employed to-day. On the one hand, a far wider range of underlying sciences is brought into requisition in the treatment of educational problems. Thus not only psychology and philosophy, but also biology, physiology, sociology, and economics are brought to bear on the work. On the other hand, the propagation of opinions, "arm-chair" pedagogy, has been replaced by resolute search for facts through historical research, through comparative study, through the use of experiment and statistical methods. The department of education brings to scientific research a set of interesting practical problems and to the schoolmaster a mass of incontrovertible facts and conclusions that cannot fail to prove of practical use.

It is interesting to note that the term pedagogy bids fair to be revived in the title "experimental pedagogy." This science springs not so much from the desire of the schoolmaster or the educational reformer to establish teaching on an unshakable basis, as from the tendency on the part of experimental psychology to reach out into new fields, especially those where its methods and principles can be made to bear on the practical world. But, although somewhat different in its origin from genetic and educational psychology, which began as attempts to get a scientific basis for teaching rather than new problems for science, experimental pedagogy naturally tends to include both these forerunners. E. N. H.

See EDUCATION, ACADEMIC STUDY OF; EXPERIMENTAL EDUCATION; PSYCHOLOGY, EDUCATIONAL; PHILOSOPHY OF EDUCATION; also CHILD STUDY.

PEDAGOGY, DOCTOR OF.—See DEGREES.

PEDANTRY.—A term given to the display of knowledge for the sake of its display, especially in the exhibition of knowledge upon unusual topics and subjects irrelevant to current needs and interests and hence lacking application. Probably one indispensable factor in pedantry is that the knowledge exhibited be second hand, or show dependence

upon somewhat antiquated authorities, being more or less accompanied by quotations from them. Knowledge that seems vital and important at one epoch may seem a useless affectation at another. At the Renaissance, reformers like Montaigne (*q.v.*) and humorists like Rabelais (*q.v.*) found most scholastic scholarship to be mere pedantry while the successors of the humanists regarded as pedantry the humanists display of classical allusions and Ciceronian Latinity. Such historic illustrations show that the question underlying pedantry is the readaptation of the learning of the past to contemporary conditions. J. D.

PEDICULOSIS.—See INFECTIOUS DISEASES.

PEDOLOGY.—See PARENTHOOD, EDUCATION FOR.

PEET, HARVEY PRINDLE (1794-1873).—Educator of the deaf; graduated from Yale College in 1822, having previously taught in the district schools of Connecticut. He was an instructor in the American Asylum for the Deaf at Hartford from 1822 to 1831, when he was called to the principalship of the New York Institution for the Deaf. He prepared a series of textbooks for the use of deaf children and published many papers on the education of the deaf, which were collected and published with the title *Summary of the Recorded Researches and Opinions of H. P. Peet* (Washington, 1873). W. S. M.

See DEAF, EDUCATION OF THE.

References:—

BARNARD, H. *American Journal of Education*, Vol. III, pp. 366-382.
See also the *American Annals of the Deaf and Dumb* for 1873

PEIRCE, BENJAMIN (1809-1880).—Mathematician and textbook author; graduated from Harvard University in 1829. He was for two years associated with George Bancroft (*q.v.*) as a teacher in the famous Round Hill School (*q.v.*) at Northampton, Mass. From 1831 to his death he was tutor and professor at Harvard. His publications include: *Plane and Spherical Trigonometry* (1835), *Algebra* (1837), *Plane and Solid Geometry* (1837), *Miscellany of Mathematics and Physics* (1842), *Analytic Mechanics* (1855), and many papers on mathematical science. He was also the author of the *History of Harvard University from its Foundation in the Year 1636 to the Period of the American Revolution* (1833). W. S. M.

PEIRCE, CYRUS (1790-1859).—Principal of the first state normal school organized in the United States; graduated from Harvard College in 1810. He taught for two years and

then studied for the ministry. He was in the service of the church for eight years; "he abandoned the pulpit for the desk of the teacher." He taught four years at Andover and nine years at Nantucket. On the organization of the first state normal school at Lexington (now at Framingham), Mass., in 1839, he was chosen by Horace Mann as principal. "Only three students presented themselves at the opening of the school," but the earnestness and skill of Mr. Peirce "soon attracted attention; and the apathy with which his labors were regarded by many friends of education gradually gave place to confidence." The normal school was removed to West Newton in 1844 and to Framingham in 1849. W. S. M.

PENMANSHIP.—See WRITING.

PENN CHARTER SCHOOL.—See FRIENDS, EDUCATIONAL INFLUENCE OF THE SOCIETY OF.

PENN, WILLIAM (1644-1718).—Founder of Pennsylvania; studied at Christ College, Oxford, but was fined and expelled for "the sin of nonconformity," having connected himself with the Society of Friends. He continued his education in France, and in 1681 obtained grants of land in America which he organized into the colony of Pennsylvania. Before leaving England, he stipulated that the governor and provincial council of the new colony "shall erect and order all public schools and reward the authors of useful sciences and laudable inventions." In the charter granted by Penn in 1711 he emphasized the importance of a "good education of youth, and their early introduction in the principles of true religion and virtue, and qualifying them to serve their country and themselves by breeding them in reading, writing, and learning of languages and useful arts and sciences, suitable to their sex and age and degree." His important educational writing is *Charter of ye Publik School founded in ye Town and County of Philadelphia in Pennsylvania* (Philadelphia, 1701). W. S. M.

See FRIENDS, EDUCATIONAL WORK OF SOCIETY OF; PENNSYLVANIA, STATE OF.

PENNSYLVANIA COLLEGE

PENNSYLVANIA COLLEGE FOR WOMEN, PITTSBURGH, PA. — Founded in December, 1869, by persons interested in promoting the higher education of women in this region. In addition to the academic department leading to all regular college degrees, there is a music department offering courses in connection with regular college work and a special music course leading to a certificate. A department of social service has been organized recently giving special training to social workers who wish to enter paid work or to give intelligent services as volunteers, and the course combines theoretical study and practical work. Pittsburg, with its great industries and its diversified philanthropies, is an unusual field for observation, investigation, and practical work; many of the institutions cooperate with the college, and experienced social workers give individual assistance. The entrance requirements to the college courses which lead to the degree of A.B. are four years' work of a high school. The social life receives much attention from the point of view of individual training. The faculty consists of eighteen members and the enrollment of students, excluding those in the department of music, was 134 in 1910-1911. C. H. C.

PENNSYLVANIA COLLEGE, GETTYSBURG, PA. — A nonsectarian institution, founded and fostered by the General Synod Lutheran Church, chartered by the legislature of Pennsylvania in 1832. The impulse which led to the founding of the college came from the Lutheran Theological Seminary established in Gettysburg six years earlier. Thus, while the primary motive was to furnish a thorough preparation for the men contemplating the seminary course in theology, the general object of the founders was the promotion of academic and scientific education under Christian influences. The course of study, as originally planned, covered the subjects of philosophy, Latin, Greek, natural science, mathematics, English, and German, leading to the degree of A.B. From 1840 to 1861 a medical department, located at Philadelphia, was connected with the college. In 1884 the scientific department was organized, leading to a division of the course into classical and scientific. During recent years a number of new courses have been added, offering a wider range of choice and differentiation of courses of study. There are at present (1912) nine group courses, determined by the major course of study, leading to the Bachelor's degree. The fourteen units recommended by the committee of uniform college entrance requirements are required for admission to the freshman class. The school is controlled by a self-perpetuating board of trustees consisting of thirty-six members. The grounds and equipment are valued (1912) at \$660,000

PENNSYLVANIA, STATE COLLEGE

including a library of 25,000 volumes. The productive endowment amounts to \$225,600. The total income for the year ending July 1, 1911, was \$41,877.46. The enrollment in 1910-1911 was 323. Women have been admitted since 1886. The teaching force numbers 23. C. F. S.

PENNSYLVANIA MILITARY COLLEGE, CHESTER, PA. — An institution organized in 1862 as the Pennsylvania Military Academy, and located at Chester in 1865. The college was the outgrowth of a private boarding school established at Wilmington, Del., in 1821. Military instruction was introduced in 1858. In 1892 the academy adopted the present title. Preparatory and collegiate (civil engineering, chemical, and academic) departments are maintained. Definite entrance requirements are not stated. Degrees are conferred. The enrollment of collegiate students in 1911-1912 was 104; and the faculty consisted of fifteen members.

PENNSYLVANIA, STATE COLLEGE OF, STATE COLLEGE, PA. — Was established by the "Morrill Act" passed by Congress July 2, 1862, and a reciprocal act of the legislature of Pennsylvania passed April 1, 1863. As early as 1855 a charter had been issued to certain public-spirited citizens under the patronage of the state Board of Agriculture, and in 1859 an institution for secondary agricultural education was opened at the present location under the name of "The Farmers' High School," the first class being graduated in 1861. Under the new establishment, the name was changed in 1874 to The Pennsylvania State College. Some of the trustees are *ex officio* state officials; others are appointed by the Governor; others are chosen by the alumni of the college; and still others are elected by delegates from industrial organizations of the state.

The growth was small until 1887, when the state began a regular biennial appropriation to the institution, the total of which now (1911) aggregates \$3,565,726.43. The most recent appropriation was \$800,000. The growth in total attendance of students by decades is as follows: 1891, 209; 1901, 433; 1911, 2007. The present force of instructors numbers 190. No tuition is charged, but preference in admission is given to residents of the state. A very small percentage of the students come from other states and foreign countries. Fourteen units are required for entrance to the college.

There are five schools, viz. agriculture, engineering, liberal arts, mining, and natural science; also one department, home economics. In these schools thirty-six courses of study are offered leading to the Bachelor's degree. Courses are also offered leading to the Master's degree. Correspondence work is confined to lessons on agricultural topics, in which

3600 students are now enrolled, and to students in the Summer Session who wish to continue their instruction.

Six hundred acres of farm land are owned by the college, part of which is devoted to experimental farming, part to forestry wood lots, and part to campus. The total value of land and buildings is \$1,444,369.

The college differs from other institutions mainly in its rural environment which develops a solidarity of college sentiment, a harmony of college life, an effective system of student self-government, an economy in style of living, and a devotion to the more serious aspects of college residence. Attendance on chapel service is compulsory, many Bible classes are maintained, and the Christian Association has an active membership numbering 1200. There are ten chapters of national fraternities, most of whom own chapter houses in which their members reside. Edwin Erle Sparks, Ph.D., LL.D., is the president of the college.

E. E. S.

PENNSYLVANIA, STATE OF. — One of the largest and most important of the thirteen original states. First settled along the Delaware by the Swedes in 1638, it was taken over by the Dutch in 1665, and by the English in 1674; later, granted to William Penn as a proprietary colony by Charles II in 1681 and settled by him in 1682. Pennsylvania continued under Penn's charters of 1682 and 1701 up to the Revolution, and was the second state to ratify the Federal Constitution, in 1787. It has a land area of 44,832 square miles or about the size of England proper. For administrative purposes the state is divided into the city of Philadelphia and sixty-six counties, and the counties are in turn divided into city, town, borough, and township school districts. In 1910 Pennsylvania had a total population of 7,665,111, one fifth of which was in the city of Philadelphia, the density of population was 171 persons per square mile.

Educational History. — Penn's first charter, drawn up in England in 1682, provided that "the Governor and provincial council shall erect and order all public schools, and encourage and reward the authors of useful sciences and laudable inventions in the said province" and provided for "a committee of manners, education, and arts" to prevent "all wicked and scandalous living" and to see that the youth were "trained up in virtue and useful knowledge and arts." It was further agreed upon, in England, as a law for the colony, "28: That all children within this province of the age of twelve years shall be taught some useful trade or skill, to the end that none may be idle." The first general assembly of the colony, sitting at Chester in December, 1682, adopted these provisions. The second provincial assembly, sitting in Philadelphia in 1683, provided further "that all persons in this prov-

ince and territories thereof having children, and all guardians and trustees of orphans, shall cause such to be instructed in reading and writing, so that they may be able to read the Scriptures and to write by the time they attain to twelve years of age, and that they be taught some useful trade or skill," and imposed a fine of £5 per child for failure to comply, unless the child was incapacitated for learning "in body or understanding." This law was so much in advance of ideas then current in England that it was disapproved by William and Mary, but was enacted by the Governor and the assembly in 1693. The law appears to have been enforced in a few places for a time, but soon became a dead letter and was omitted entirely from the revision of 1696.

In 1683 Enoch Flower was engaged as school-master at Philadelphia, and this was the first regular school established in the state. In 1689 a "Friends' Public School" was opened in Philadelphia, after the type of a public grammar school of the time in England. This was chartered in 1697, and again in 1701, 1708, and 1711, and evolved into the William Penn Charter School. This school has been continuously in existence since 1689, and ranks as one of the oldest schools in America. Another school was established at Darby in 1692, and in 1697 the Society of Friends established a second school in Philadelphia, which took poor scholars free, and was the first public free school established within the state. But few other schools seem to have been established, and but little colonial legislation of any kind occurred after 1700. "The first three quarters of the eighteenth century," says Wickersham, "are almost a perfect blank as far as anything was done by the public authorities to provide an education for the people."

Before the Revolution many parochial schools were established by the different denominations, with the clergy frequently as the teachers; private pay schools were established in the towns and cities, and the beginnings of free education for the poor were made. Some of the private schools thus established, such as the Germantown Academy (1761) and the Moravian schools at Bethlehem and Nazareth, founded still earlier, attained a wide reputation and drew pupils from other colonies. The educational policy which developed early was that of depending upon parochial and private efforts, of making no attempt to provide any form of education for those who could pay for it themselves, and of extending charitable education to but a limited number and for a limited time.

A marked exception to these conditions was found among the settlers from Connecticut, and other parts of New England, who settled in the Wyoming Valley, in north-eastern Pennsylvania. These people brought with them from New England their political

independence and their zeal for education. The result was that they were politically troublesome and educationally efficient. In 1768 it was decreed that each township within the settlement should reserve 960 acres of land "for the public use of a gospel ministry and the schools." This was done, and, though there were some losses, the schools derived benefit from the greater part of the reservation, and some schools to-day still receive income from these old grants. School committees were elected by the inhabitants, for each school district, and these in turn employed the teacher, supervised the school, and collected a rate-bill form of tax to pay the teacher. There was also a township tax to provide schoolhouses, and in some cases also to pay teachers. The schools thus established continued in operation until the adoption of the first state school law in 1834, were the nearest approach to public schools of any established before that date in the state, and exercised considerable influence in shaping the new Pennsylvania law.

In 1776 the first constitution made liberal educational provision. Schools were ordered to be established in each county, "with such salaries to the masters, paid by the public, as may enable them to instruct youth at low prices; and all useful learning shall be duly encouraged and promoted in one or more universities." Practically nothing was done under the provisions of this constitution.

Pennsylvania ratified the Federal Constitution in 1787, and in the first constitution adopted after that, in 1790, the early liberal provision was withdrawn, and a provision for the establishment of charity schools was inserted in its stead. The legislature was directed, "as soon as conveniently may be," to provide by law "for the establishment of schools throughout the state, in such manner that the poor may be taught *gratis*." The "rights, privileges, immunities, and estates of religious societies and corporate bodies" were guaranteed, as before, and the promotion of "the arts and sciences" was directed, "in one or more seminaries of learning." These provisions were continued unaltered in the new constitution of 1838.

An act of 1802 made the first provision for carrying these constitutional mandates into effect. This gave to the overseers and guardians of the poor the task of selecting the children who were to receive a charitable education, and of collecting the money, by an increase in the "poor rates," with which to provide their books and tuition. In 1809, in an effort to remove the pauper taint, the administration of the law was given to the township assessors and county commissioners, but without success in eliminating the name of "pauper schools." In 1824 an effort was made to substitute a form of a public for a pauper school system, by a law which provided for an election in each township, borough, or ward,

which should accept the law, of a board of three school men, one to be elected each year. This law was too advanced to stand, and two years later it was repealed and the old pauper school law of 1809 was substituted for it. In this condition matters remained until 1834. During the first forty years of statehood, the chief educational legislation was in the form of private incorporation acts for schools and colleges, a number of which were granted some state aid. By 1830 as many as 133 such special acts had been passed, and in 1833 there were two universities, eight colleges, and fifty academies which had been aided, to some degree, and mostly in return for the education of poor children, by grants from the state.

A few movements looking toward a state public school system were made early in the century. In 1812 the City Council of Philadelphia and the County Commissioners, acting jointly, were permitted to take such action as the public good might require toward the establishment of schools; in 1814 "The Society for the Promotion of a Rational System of Education" was organized in Philadelphia; in 1818 the City of Philadelphia was organized by special law, as the first school district of Pennsylvania, and permission was given to provide Lancasterian schools for the education of the poor (see PHILADELPHIA, CITY OF; also LANCASTER, JOSEPH); in 1821 the counties of Dauphin (Harrisburg), Allegheny (Pittsburg), Cumberland (Carlisle), and Lancaster (Lancaster) were also exempted from the operation of the pauper school law; in 1822 the city of Lancaster was organized by special law, as the second school district of Pennsylvania; and Governors of the state, in their messages to the legislature from 1801 on, made repeated recommendations that some further action be taken to carry into effect the constitutional mandates and to provide better educational advantages for the children of the state. In 1822 the Committee on Education of the Senate reported that the Act of 1809 was wholly inoperative in many counties, and much abused in others, and a report made to the House of Representatives in 1829 showed that there had been educated free, in the 31 counties reporting, but 4940 poor children in 1825; 7943 in 1826; 9014 in 1827; and 4477 in 1828. In 1833, the last year of the pauper school system, the number of free pupils educated was 17,467, and the total cost but \$48,466 25.

The bill establishing the State Common School Fund, 1831, provided for the addition of the income from the sale of public lands, and the interest on the same, until a fund of \$2,000,000 should be reached, after which the income should be applied annually to the maintenance of schools. It was estimated that this would be in about ten years, but, in 1834, the friends of education succeeded in passing a bill which made the beginnings of

a state school system at that time. This act contained many of the provisions of the law of 1824, and the unsuccessful bills of 1831 and 1833. Each county was made a school division, and each ward, township, and borough a school district. For each school district a board of six school directors was to be elected by the people, one third of whom should go out of office each year. Each county court was to appoint two inspectors for each district, and the Secretary of State was made *ex officio* Superintendent of Public Schools. The income from the state school fund was to be supplemented by a state appropriation of \$75,000 and by county and local taxation; though any district might decide to raise no tax for free schools, forfeit its state apportionment, and fall back on the provisions of the old 1806 law for the maintenance of pauper schools.

The provisions here made for free schools, and for secular schools at that, seemed almost revolutionary at the time, and the law was vigorously attacked in the next legislature. Petitions asking for the repeal of the law, signed by 32,000 voters, mostly signed in German script, were presented. The House leader was Thaddeus Stevens, to whom the credit for saving the law has been given. An act of 1836 revised and strengthened all preceding legislation, and laid down the main lines along which the school system of Pennsylvania later developed.

The new school system was accepted but slowly. During the first year of its operation, 536 out of 907 districts accepted the system, 762 schools were conducted, and an average term of $3\frac{1}{2}$ months was provided. During the next two years, the *ex officio* State Superintendent did much to explain the new system and to secure its acceptance by the people, so that by 1838 the number of districts accepting the new system had increased to 861, out of a total of 1033. By 1847, the last year of the old system, 1105 of the 1249 districts had accepted the system. It was not until 1873, however, that the last district surrendered and accepted the state school system. In 1837 the United States Surplus Revenue (see NATIONAL GOVERNMENT AND EDUCATION) was received, and for two or three years very material aid was given to the new school system by appropriations from this fund, to be used for buildings and yearly maintenance. Probably about \$800,000 was derived from this source before the fund was all spent; the aid was no doubt timely and helpful, as the people were not yet willing to bear taxation for schools.

In 1838 the state attempted to systematize the grants for universities, colleges, academies, and female seminaries, which had been made from time to time for nearly half a century, by a general law granting annual state aid to all such institutions meeting certain con-

ditions. The grants were to run for ten years, but in 1843 they were cut in half, and in 1844 entirely abandoned. In 1840 school directors were authorized, directly or by the aid of competent persons, to examine and certificate all teachers. In 1843 directors of city, ward, or borough school districts were authorized to employ district superintendents, and in 1849 this provision was extended to all state-aided districts. Few superintendents were ever employed, and the law was superseded in 1854 by the law providing county supervision. The elections of 1848 being so favorable (about 90 per cent for), the legislature in that year extended the school system to include all school districts. It was twenty years, however, before public schools existed in all of the school districts of the state. In 1849 the laws were recodified, and the minimum term extended from three to four months. This created so much opposition, however, that in 1851 the law was in part repealed. In 1836 Philadelphia had been authorized to establish a high school; similar permission was granted to Pittsburgh in 1849, and to Easton in 1850; and in 1854 all doubt as to the legality of districts establishing such schools was removed by a general law, authorizing the establishment of "graded schools and the study of the higher branches."

In 1850 a state convention of the friends of education was held in Harrisburg. The proceedings and resolutions of this convention, published by direction of the legislature, were made a platform for educational advancement, and did much to secure the new law of 1854. In January, 1852, the first number of the *Pennsylvania School Journal* was issued, and in 1855 was made the official organ of the State Educational Department. In 1852 the State Teachers' Association was organized at Harrisburg. Teachers' institutes were now organized in a number of counties, and other conventions held. The result of this awakening was the new school law of 1854, which reorganized the system. By this law the township was made the unit of the system, and districts were given corporate powers; the minimum school term was again increased to four months, and separate schools for negroes were required, where practicable; a district tax for school buildings and the publication of a book by the State Superintendent on school architecture were authorized; reading, writing, spelling, grammar, geography, and arithmetic were made statutory school subjects, thus doubling the course of instruction in many districts; school directors and teachers were directed to adopt textbooks for the district; grants for instruction to endowed and to religious schools were prohibited; and the offices of county superintendent of schools for each county and of deputy superintendent of common schools were created. In 1857 the office of State Superintendent was detached

from that of Secretary of State, a separate department of common schools was created, and a State Superintendent of Common Schools, to be appointed by the Governor for three-year terms, was provided for. The year 1857 also marked the first provision for the education of teachers made by the state. The state was divided into twelve normal-school districts (increased to thirteen in 1874), in each of which a normal school was eventually to be established. In 1859 the Lancaster County normal school, at Millersville (opened in 1855), was recognized as the first state normal school; in 1861 the school at Edinboro, in 1862 the school at Mansfield, and in 1866 the school at Kutztown, were similarly recognized. By 1877, ten schools had been recognized, and the thirteenth was added in 1893. These schools, private in nature, received state aid for buildings and for each pupil trained.

In 1863 an attempt was made to change the basis of apportioning state aid from taxables to school census, but the returns were so unreliable that the taxable basis was restored in 1864. In 1864 the first school library law was enacted. By 1866 the teachers' institutes, begun after 1850, had extended to twenty-three counties of the state, and in 1867 they were legalized and required for all counties with county aid. By the law of 1867, cities and boroughs having a population of 10,000 were permitted to employ city superintendents; the right of eminent domain was granted to districts; the old "provisional certificate," based on an examination in reading, writing, and arithmetic only, was abolished, and all teachers were required to pass an examination in reading, writing, spelling, arithmetic, geography, grammar, United States history, and the theory of teaching; county superintendents were required to hold a teacher's certificate, or to be a graduate of a college or a normal school; and the state permanent teachers' certificates were also authorized. In 1864 the Pennsylvania Soldiers' Orphan Schools were organized, and in 1871 the Pennsylvania Training School for the Feeble-minded was established at Media. In 1872 the minimum school term was increased to five months.

In 1873 a new state constitution was adopted, and in this the progress made during the preceding forty years was recorded and somewhat extended. After the adoption of the new constitution, no new code of laws was enacted, the schools continuing under the laws of 1854 and 1876, with various minor amendments, until the adoption of the new school code in 1911. In 1881 the requirement of separate schools for the races, instituted in 1854, was withdrawn, with but little resulting change. In 1883 an evening school law was enacted. In 1885 physiology and hygiene were added to the list of examination subjects for teachers' certificates, and in

1901 civil government and elementary algebra. In 1887 teachers were first paid for attending teachers' institutes, and separate city teachers' institutes were authorized. In 1893 a district free-textbook law was enacted, the county superintendents' salary law (first enacted in 1878) was revised, and state teachers' certificates were first granted to college graduates. In 1895 there was quite an amount of legislation with regard to district lines, district indebtedness, and district boards; boards of directors were permitted to establish free public libraries, and to levy a one-mill tax for their support; a vaccination law and an anti-religious-garb law were enacted; and joint high schools were authorized, state aid for high schools extended, and the State Superintendent instructed to prescribe a uniform high school course. In 1897 the distribution of state aid was finally changed from the old basis of taxables to a plan based on a combination of teachers, taxables, and school census; stenography and typewriting and kindergartens were authorized; the transportation of pupils was permitted; and a schoolhouse flag law was passed. In 1899 the minimum school term was extended from six to seven months, and a State Free Library Commission was established. In 1901 township centralization, with the transportation of pupils, night manual training schools, and township supervising principals were authorized. In 1907 a minimum salary law, with state aid to weak districts, a school sanitation law, and an annual school directors' convention law were enacted. In 1909 the child labor law was revised and materially strengthened, and a detailed law relating to the handling of school diseases was enacted.

In 1907 the legislature passed a law directing the Governor to appoint an educational commission, to revise and codify the school laws of Pennsylvania. A carefully revised code was prepared and submitted to the legislature of 1909, passed by the legislature, but vetoed by the Governor. The same commission submitted a similar code to the legislature of 1911, and this finally became a law.

Present School System.—At the head of the present school system of Pennsylvania, as reorganized in 1911, is a State Board of Education, and a State Superintendent of Public Instruction. The State Board of Education consists of six citizens, appointed by the Governor (the members of the educational commission were appointed as the first State Board) with the concurrence of two thirds of the Senate, and for six-year terms, one going out of office each year. The State Superintendent of Public Instruction, also appointed by the Governor, for four-year terms, is *ex officio* a member and president of the State Board. The members serve without pay, and one half of them must be experienced educators, connected with the

public school system of the state. The Board has important duties, largely advisory, and important business functions, and it may elect such officers, employ such assistants, and incur such expense, as it deems necessary. All schools in the state, of whatever kind, supported in whole or in part from state sources, must report to the Board. It may make such by-laws and prescribe such rules and regulations for the sanitary inspection and equipment of schools as it may deem necessary. It is charged with the care and management of the state school fund and with the promotion of agricultural, vocational, and industrial education in the state. For this purpose, and also for the equalization of educational advantages throughout the state, the Board may use so much of the income of the state school fund as it sees fit. It is charged with the purchase of the thirteen normal schools of the state from the stockholders, and thereafter with the appointment of trustees for the schools purchased. The Board is directed to prepare and publish schoolhouse plans, and to furnish them free to districts, and all plans for the construction or reconstruction of buildings, except in first-class districts (Philadelphia and Pittsburg) must be approved by the State Board. The Board makes an annual report to the Governor as to its work and as to the condition of the state school fund, and the Board is also instructed to recommend needed legislation to the Governor and the legislature.

The State Superintendent acts as the executive officer of the Board and has more than the usual functions of this officer. He appoints all of his deputies and assistants, consisting of two deputy superintendents, three experts in agricultural education, industrial education, and drawing, four inspectors of elementary and high schools, and all necessary clerks, and at salaries fixed by law.

For each of the sixty-six counties a county superintendent is elected, for four-year terms, by a convention of all the school directors (trustees) in the county representing districts not employing a city or town superintendent. Assistant superintendents must possess the same qualifications as county superintendents, and are appointed for the same length of time. They assist the county superintendent in the supervision of instruction, the inspection of grounds and buildings, the approval of courses of study, the conferring with directors, and the examination of pupils and schools, and may act for him, as directed. They also examine teachers for the schools of their counties.

Each county is divided into a number of school districts, each city, incorporated town, borough, or township constituting a separate school district, coterminous with the civic division. All independent school districts were abolished in 1911, though provision for their temporary reconstitution was made. All

districts are divided into four classes, as follows: 1st, population of over 500,000,—board of 15; 2d, population of 30,000 to 500,000,—board of 9; 3d, population of 5000 to 30,000, board of 7; 4th, population of less than 5000,—board of 5. There are but two first-class districts, Philadelphia and Pittsburg, and for a description of these and their powers, see special article on PHILADELPHIA, CITY OF. For the other classes of districts, the boards of school directors are elected at large, and for six-year terms, approximately one third going out of office each year. Each district is a school corporation, and the title of all school property is vested in the school district. First and second-class districts must, and third-class districts may, appoint a district (city) superintendent of schools for a four-year term, after which such districts are not under the supervision of the county superintendent of schools. The district superintendent must be commissioned by the State Superintendent, and succeeds to all the duties and powers of the county superintendent. Any third or fourth-class district may appoint a supervising principal. Each board of directors must provide a sufficient number of schools to educate all children six to twenty-one, and they also have the power to provide high schools, evening schools, kindergartens, vocational schools, libraries, museums, playgrounds, special class schools, truant and parental schools, schools for adults, and such other schools as they deem desirable. On petition of the parents of twenty-five children over fourteen, they must provide an evening school, and on petition of seventy-five taxpayers, they must provide an evening manual training school. Any board may establish an agricultural school, and admit those over twenty-one to any vocational classes. Each board also has the power to levy taxes, within fixed limits, for all school purposes; may, similarly, borrow money, and issue bonds; may acquire real estate; may make and enforce all reasonable rules and regulations; may appoint and, for proper cause, may remove teachers and all other employees; in first- and second-class districts must, and in third- and fourth-class districts may, control all student activities and publications; must furnish the textbooks and supplies needed, and may loan books to pupils during vacations; are to adopt courses of study, with the approval of the district or county superintendent; may provide transportation for pupils, or may consolidate schools, or may do both; must take and report an annual school census; and must maintain all schools in the English language. Textbooks are adopted by the boards for five-year periods, and no change can be made, without the recommendation of the superintendent, except by a two thirds vote.

School Support.—The schools are sup-

ported by a state appropriation and by local taxation, the latter comprising about 80 per cent of all income for maintenance. The state appropriation was about seven million dollars at last report, and this is distributed to the districts (since 1911) on the combined basis of one half on teachers actually employed and one half on school census. The state school fund, created in 1911, is to consist of 80 per cent of the net income from the state's forest reserves (estimated at 1,000,000 acres), the income from the state's water-power rights, the income and proceeds from all state lands not used for public purposes, all escheated estates, and all property or money given to the fund. The State Board of Education is to use so much of the income as they deem wise, to equalize educational advantages in the state, and to aid education in forestry, agriculture, and industrial pursuits, and then to add the remainder of the income to the principal of the fund. Under the new law, each district levies its own school taxes. In first-class districts, the levy must be between five and six mills, in second-class districts not over twenty mills, and in third- and fourth-class districts not over twenty-five mills.

Teachers and Training. — Three grades of teachers' certificates are issued, — provisional, professional, and state. Each must state on its face the subjects of the examination, for which alone it is valid. No teacher may teach any subject not named on the face of the certificate, so that this virtually creates a form of high school certificate. Each superintendent, county or district, may examine and certificate teachers for his own county or district. Provisional certificates are valid only in the district where issued, and for one year, and no teacher may teach on such over five years. Professional certificates presuppose two years' experience, more advanced examinations, are renewable three times, and may be granted inter-county recognition. State certificates are valid throughout the state, and presuppose two years of teaching on a professional certificate, or college or normal school graduation. Full recognition is granted to college and normal school graduates, and good inter-state recognition of certificates prevails. A certificate cannot be issued to a person addicted to the use of drink and narcotics, not physically and mentally sound, or not of good character, and any certificate issued may be annulled for cause. The reading of pedagogical books designated by the State Superintendent is emphasized in the granting of all higher certificates. Any district may create or contribute to a teachers' retirement fund. A minimum salary law for teachers insures a salary of \$60 or \$65 a month, according to the certificate held.

For the training of future teachers, the state subsidizes and exercises a partial control over thirteen so-called state normal schools. The

new school code contemplates the purchase of each of these joint-stock institutions, authorizes the State Board of Education to negotiate purchases, and directs each legislature to appropriate \$200,000 for the purpose, until all of the thirteen schools are acquired. Philadelphia, Pittsburg, and Reading maintain city normal schools.

Educational Conditions. — A good medical inspection law was incorporated in the new code, by which all first- and second-class districts must provide for medical inspection, third-class districts must also, unless they vote annually not to do so, and fourth-class districts are to be provided with medical inspection by the State Commissioner of Health, unless they notify him in writing each year that they do not want it. Any district board may also appoint a school nurse. Detailed reports are to be filed and copies sent to parents. The sanitary inspection of buildings is also a part of the work. All school buildings must meet certain hygienic conditions, and all two-story buildings must be fireproof. All deaf, dumb, blind, and mentally deficient children must be reported to the medical inspector for examination, and their proper education provided for.

All first- and second-class districts must provide a school term of 9 months, third-class districts of 8 months, and fourth-class districts of 7 months. All schools must be taught in the English language. Textbooks and supplies are furnished free by the districts. All children 6 to 21 may attend school, and all children 8 to 14 must attend a public or accepted private school every day the public schools are in session, except that in fourth-class districts the directors may vote to reduce the required time to 75 per cent of the school term. All children 14 to 16 not properly employed must also attend school, and those at work must possess employment certificates. Children 8 to 14 cannot be employed at any labor during school hours. All first-, second-, and third-class districts must appoint attendance officers, and fourth-class districts may do so. Two or more districts may join in the appointment of an attendance officer, and the State Superintendent may withhold state funds from districts failing to enforce the law. No religious or political test can be required in the schools, and the requirement of separate schools for the negro race is forbidden.

Secondary Education. — Three classes of high schools are recognized, and state aid is granted for each class. A first-class high school must provide 4 years of instruction, a 9 months' term, employ at least 3 teachers, and receives a maximum state grant of \$800. A second-class high school must provide 3 years of instruction, an 8 months' term, and employ at least 2 teachers, and receives a maximum state grant of \$600. A third-class high school must provide 2 years of instruc-

tion, and receives a maximum state grant of \$400. Any school district may establish a high school, as it sees fit, except that in fourth-class districts the approval of the county and State Superintendents must first be obtained. The course of study must be approved by the superintendent of the district or the county. Joint district high schools are provided for, with joint high school boards. Children not residing in high school districts, or full four-year high school districts, may attend neighboring schools, their tuition being paid by their home districts. All school districts have the same power to establish and support high schools as they have for elementary schools, there being no separate high school funds. The high schools have developed rapidly during the past ten years. In 1902 there were but 66 township high schools, while in 1910 the number had increased to 332. The same year there were 508 borough and city high schools. There were 125 first-class, 236 second-class, and 479 third-class schools in the state.

Higher Education.—The Pennsylvania State College (*q.v.*), located at State College in central Pennsylvania, is the only institution of higher learning maintained by the state. This institution, founded in 1859, offers instruction in agriculture, engineering, and household economy. The University of Pennsylvania (*q.v.*) receives some small state aid, but it is essentially a private foundation. The central high school in Philadelphia and the University of Pittsburgh are municipal institutions. The state has a large number (34) of non-state colleges, mostly on religious foundations, twelve of which date back to before 1850. Some of these, as for example Muhlenberg, Dickinson, Lafayette, Haverford, Franklin and Marshall, Bucknell, Lehigh, Swarthmore, Washington and Jefferson, and Bryn Mawr (*qq.v.*), possess considerable property and offer a good grade of collegiate instruction. About one half of the number are open to both sexes, six are for women only, and one is for the colored race.

Special Education.—For the education of delinquents, dependents, and defectives, the state maintains, in whole or in part, the following special state institutions:—

Pennsylvania Industrial Reformatory, at Huntingdon.
 Pennsylvania State Reform School, at Morgantown.
 House of Refuge, for Girls, at Darling.
 House of Refuge, for Boys, at Glen Mills.
 Pennsylvania Institution for the Blind, at Overbrook.
 West Pennsylvania Institution for the Blind, at Pittsburgh.
 Pennsylvania Institution for the Deaf and Dumb, at Philadelphia.
 West Pennsylvania Institution for the Deaf and Dumb, at Edgewood Park.
 Pennsylvania Oral School for the Deaf at Seranton.
 Pennsylvania Home for the Training of Deaf Children before they are of School Age, at Philadelphia.
 Pennsylvania Training School for the Feeble-minded, at Elwyn.
 State Institution for the Feeble-minded of Western Pennsylvania, at Polk.

PENNSYLVANIA, THE UNIVERSITY OF, PHILADELPHIA, PA.

—This university had its origin in a tract written by Benjamin Franklin, entitled "Proposals relating to the Education of Youth in Pensilvania." Soon after its publication, twenty-four public-spirited citizens of Philadelphia associated themselves for the purpose of establishing an academy, and "laying a Foundation for Posterity to erect a Seminary of Learning more extensive and suitable to their future Circumstances." The board chose Franklin for its president and directed him with the aid of the attorney-general to draw up a constitution. One of the first acts of the board was to secure the use of a building erected at Fourth and Arch Streets, Philadelphia, by a trust founded in 1740, and intended to serve for a "Charity School" and a "House of Publick Worship." For the latter purpose the structure was used in November of 1740, when Whitefield first preached in it; the charity school, however, was never set in operation. The trustees, in order that their trust might be carried out and the building "applied to the good and pious uses originally intended," conveyed it, on February 1, 1750, to the trustees of the Academy by an indenture, which bound the latter to keep a "House of Publick Worship" and "one free school" for the instruction of poor children; but empowered them, so long as they preserved the aims of the original trust, to employ the property as they saw fit. In January, 1751, the Academy was formally opened. It embraced three schools, English, Latin, and Mathematical, over each of which sat a master, one of whom was rector of the institution. The Academy met with marked success, and upon application readily secured from Thomas and Richard Penn, the Proprietors, a charter in 1753.

William Smith, first Provost of the University, began his administration in 1755. The scope of the Academy rapidly widened. In 1755, at the request of the Board of Trustees, Governor Morris granted a second char-

ter which confirmed the first, granted power to confer degrees, and changed the title of the board to "The Trustees of the College, Academy, and Charitable School of Philadelphia." The first commencement of the College, with a graduating class of seven young men, took place in May, 1757. After this its name and influence spread widely and it drew support from Maryland, Virginia, the Carolinas, and the West Indies. Dr. Smith planned the curriculum in 1756 to extend over three years, and to include Latin, Greek, mathematics, chemistry, philosophy, history, ethics, civil and international law. This plan laid the foundation for the educational system of the American college. Dr. Smith was a man of many interests, a church worker, an educator, a scientist, and at times an active politician. In the latter capacity he incurred the displeasure of the Provincial Assembly by an alleged libel against its privileges, and was thrown into jail, where he nevertheless continued to meet his classes. In 1759 he went to England for redress, and while abroad received honorary degrees from Oxford, Aberdeen, and Dublin. In 1762 he went again to England in the interests of the College. As the result of an appeal for aid to George III, to the Penns, and to the English people, he returned to America with slightly over £6000. This favor shown by George III later militated against the College, because it confirmed the feeling then existing that the College sided with Tory interests. Objections were made to the exercise of some of the rights under its charter. As a consequence of complaints, an act of Assembly in 1779 revoked the charters of 1753 and 1755, and formed a new corporation, "The Trustees of the University of the State of Pennsylvania." In 1789 this act was repealed, as a "violation of the Constitution of this Commonwealth," by a bill which once more secured to the College its privileges and franchises with Dr. Smith as Provost. But even thus the College and the University were separate, and there was not room for two institutions. The trustees of both accordingly applied to the assembly to have the charters of each surrendered, a new corporation created, and a board of trustees, representing both College and University, organized. The Assembly passed an act in September, 1791, uniting the University of the State of Pennsylvania and the College, Academy, and Charitable School of Philadelphia under the title "The Trustees of the University of Pennsylvania."

The new organization comprised three departments, the arts, medicine, and law. The department of arts embraced five separate schools under the care of six professors and their assistants. The medical school, the first in North America, had been founded in May, 1765, when Dr. John Morgan and Dr. William Shippen presented to the trustees a plan, approved by Thomas Penn, the Pro-

prietor, for a course in medicine. Dr. Morgan was at once appointed Professor of the Theory and Practice of Physic, and Dr. Shippen, Professor of Anatomy and Surgery. In June, 1768, ten men were graduated with the degree of Bachelor of Medicine. By 1791 there were added to the medical faculty a chair of botany and *materia medica* and a chair of chemistry. The law school dates from 1790, when the trustees of the College elected to the first professorship of law in America Hon. James Wilson, then one of the Associate Justices of the Supreme Court of the United States.

Dr. Ewing succeeded Dr. Smith as Provost in 1791. During Ewing's administration the University moved from its old home on Fourth Street to a building on the West Side of Ninth Street between Market and Chestnut streets, erected by the legislature in 1791, before the removal of the National Capitol to Washington, as a home for the President of the United States. This the University bought in 1800, and occupied from 1802 to 1829, when it was replaced by two large buildings occupied respectively by the College and the Medical School until 1873, when the University removed to its present site in West Philadelphia. In 1807 Dr. Ewing died. The administrations of Provosts McDowell, Andrews, and Beaseley extended to 1828. In spite of attempted reorganizations, the classes diminished in size and public support ran low. Provosts DeLancey, Ludlow, Vethake, and Goodwin, notwithstanding their short administrations, brought to the University once more the spirit of progress and discipline. The enrollment increased, the law school was revived in 1850 by Judge Sharswood, and the auxiliary department of medicine founded in 1865.

It remained, however, for Dr. Stillé, who became Provost in 1868, to reorganize the administration. Dr. Stillé was a man of unusual zeal, energy, and insight. He revised the curriculum, and introduced on its adoption by the Board of Trustees in 1866 an elective system of studies. The Board of Trustees set about to increase the endowment. It suggested that the City should sell to the University at a nominal figure some twenty-five or thirty acres of the almshouse farm in West Philadelphia. Of this, part was to be a new site for the University, and part to be sold, as occasion should present, to increase the endowment fund. Ten acres of land were bought at \$8000 per acre. On this new ground was laid in June, 1871, the corner stone of the present College Hall. In 1875 the department of science, founded in 1852, was endowed under the provisions of the will of John Henry Towne, Esq., and was thenceforth called by the Board of Trustees "The Towne Scientific School." Five and one half acres more were secured in 1872 for the site of a hospital,

UNIVERSITY OF PENNSYLVANIA.

which through state appropriation was completed in 1874. A department of music was established in 1877, a department of dentistry in 1878. In 1877 the Charitable School was discontinued.

Dr. William Pepper became Provost in 1881 upon the resignation of Dr. Stillé. His term of office was a period of marked material and academic growth. Through enlargement of funds, creation of departments, and reorganization of faculties, Provost Pepper united the various departments of the institution under a comprehensive plan of administration. In 1881, through the generosity of Joseph Wharton, Esq., a School of Finance and Commerce was founded. (See COMMERCIAL EDUCATION.) To Dr. Pepper's activity is due in large measure the founding and equipment of the following departments or schools: the Graduate School, 1882; the School of Veterinary Medicine, 1882; the School of Biology, 1883; the Department of Physical Education, 1885; the Department of Archaeology and Palaeontology, 1889; the School of Hygiene, 1891; the School of Architecture, 1891; the Wistar Institute of Anatomy and Biology, 1892; the Museum of Arts and Sciences, 1894; and the erection of the University library building, 1889. Furthermore, he acquired twenty-five acres more in West Philadelphia and secured benefactions amounting to \$2,500,000.

Dr. Charles Custis Harrison succeeded Dr. Pepper as Provost in 1894. In the seventeen years of his administration the University underwent phenomenal growth. Provost Harrison built up the University dormitory system, which to-day includes thirty houses. To his influence, zeal, and generosity is due the erection of numerous other buildings, — the John Harrison Laboratory of Chemistry, the new medical laboratory, the law school building, the engineering building, dental hall, the new veterinary buildings, the laboratory of zoölogy, the gymnasium, and Franklin Field. In 1910 the Henry Phipps Institute for the Study and Treatment of Tuberculosis became part of the University. Furthermore, sixty-nine acres of land were acquired by the University during Dr. Harrison's term of office, and more than ten million dollars raised for University purposes. Dr. Harrison was himself a liberal giver to the University, and established in the Graduate School the George Leib Harrison Memorial Foundation. Upon the resignation of Dr. Harrison in 1910, Dr. Edgar Fahs Smith, Vice Provost and Professor of Chemistry, became Provost.

The University of Pennsylvania is a corporation with a board of twenty-four Trustees, of which the Governor of the state is President, *ex officio*. The trustees are a self-perpetuating body, except that every third vacancy is filled by the nomination of the alumni. The Provost presides over the board, in the absence of

the Governor, and directs the work of instruction and research of the University. The faculty is divided into six faculties, each presided over by a Dean. The Hospital, the Wistar Institute of Anatomy and Biology, and the Museum of Arts and Sciences are governed by boards of directors, under the general direction of the Trustees of the University. The enrollment of the University for the year 1911 was 5389, distributed as follows: The College (which includes Arts and Sciences, Architecture, Biology, Chemistry, Engineering Schools, Wharton School, and Music), 3720; Graduate School, 416; Law School, 347; the School of Medicine, 460; School of Dentistry, 462; the Veterinary Department, 154. These figures include 210 students from foreign countries. The student body is thus complex and cosmopolitan. The faculty of the University numbers 500. Entrance to the College is by examination and, only in the case of preparatory schools recognized by the university, by certificate. Entrance to the medical school presupposes at least two years of work in a recognized college, which must include special work in biology, chemistry, and physics. Admission to the law school requires of the candidate a B.A. degree, or satisfactory proof of fitness by preliminary examination. The annual budget of the University, exclusive of the hospital and of the erection of any new buildings, is \$1,250,000.

PENOLOGY, EDUCATIONAL ASPECTS OF. — The retributory theory of punishment and the death penalty have gradually retired into the background, and the educational purpose of penal institutions has correspondingly become prominent. While the primary and controlling end of the prison is to protect social order, security of person and property, the most competent practical men have come to see that society is best protected by re-educating the antisocial man in social habits, beliefs, and dispositions, if by sad mischance he has not been educated into a social character. Society breathes in comfort the hour the aggressive delinquent is safe inside the high walls; but this is from self-deception, for there is no guarantee of permanent immunity from harm until the criminal becomes a good citizen; and it is by a suitable educational pro-

cess, conducted by capable teachers, that this inward change is brought about, if at all. If education fails, nothing is left but capital punishment or life servitude in prison for the confirmed and habitual offender or the weakling incapable of training for self-control and self-support.

It is now generally acknowledged that the deterrent factor, fear of punishment, has been greatly overestimated. Fear is a weak and fitful motive, and criminals are as a class short-sighted, reckless gamblers; they are ready to take chances, and the risk of detection and conviction gives zest to the game. If society insists on the deterrent factor in punishment, the dread of regular discipline under restraint will be all that is necessary to excite and sustain the fears of lawless men.

It is a mistake to regard the educational aim as inconsistent with the fundamental aims of criminal law, and to conceive of it as purely in the individual interest of the offender himself. On the contrary, the educator keeps in mind the necessity of awakening the conscience, remorse, the recognition of an objective social order, the sense of responsibility, the rights of the public which have been willfully violated. In this sense the words "punishment," "retribution," and "deterrence" have a meaning.

Foerster, Conti, and other antagonists of the "indeterminate sentence" insist that punishment should be measured out in prison days, fines, or otherwise, and not confused with education; although they have not shown clearly and convincingly that there is any common principle for making the "punishment fit the crime." They have, however, come to see and admit that, outside of and apart from retribution and expiation, society should try to reform the offender,—only not as a part of "retribution." They have not always told us clearly whether inside the prison the State should exclude all educational and reforming influences. Certainly industry, religion, and physical care ought to work toward improvement of the moral nature and fitness for honest labor outside. Any attempt to separate education from prison life must fail. If any one chooses to call one part of the period "expiation" and another part "reformation," he is welcome to his hairsplitting logic and metaphysical satisfaction; but in actual practice the distinction cannot change the modes of treatment. A criminal is a man, and every moment of restraint and pain should be a moment of moral discipline. Until the criminal accepts the aim of education as his own, it will seem to him pure punishment and may seem expiation. If the aim of personal amendment is accepted, the restraint and suffering will seem to him an opportunity. In any case society is for the time protected and has the power to prolong restraint so long as the offender is rebellious or dangerous;

but the effort to train, teach, guide, inspire — "to educate" — must never for one moment cease. When society, in its punishment, ceases to try to reform and improve character, it lapses to that extent into barbarism; with its desire for vengeance or for compensation, the community assumes a self-corrupting attitude.

This profound change in the theory of punishment, which is going on throughout the civilized world, has begun to transform the prison, but especially the reformatory, into a school. The ideal of the warden or superintendent is slowly changing. Formerly this officer was selected with reference to his qualifications for exciting terror in the lawless and for using physical force to quell mutiny. In a well-built prison mechanical arrangements of walls, bars, and gates provide for security, and the process of education can go on inside with no more disturbance than in a high school; often with less noise and turbulence. The warden, under the best systems, is also relieved very greatly of the burden of marketing the product of prison industries and purchasing supplies; he has more time to direct the training of the prisoners; and more is expected of him in this direction. If this tendency continues, it will not be long until candidates for positions in penal institutions will be required to be graduates of normal schools and work up to the commanding position by experience in class work. Manifestly manual and trade training must be a large factor in the curriculum.

Gradually, in Europe and America, the reform school (*q.v.*) has been differentiated from the reformatory and prison. Only in backward communities is the youth under seventeen shut up with adult offenders in jail, even while awaiting trial. For wayward children and youth the penal institution has been transformed into a school having special facilities for dealing with various classes of youthful delinquents. Even bolts, bars, and walls disappear, except for the older group, which includes a few dangerous persons, and for those who are under discipline for offenses against the rules of the house.

The parental school (*q.v.*) has in some cities been introduced between the public school and the reform schools in order to give special discipline to truants and restore them to normal domestic relations without contact with more hardened offenders. This gradation and classification has been developed in advanced states in consequence of careful observation and experiment, and its value is beyond question.

Little need be said of the curriculum and management in reformatory education. It is true that the teachers must be acquainted with the physical and psychical characteristics of abnormal and subnormal children and youth, and be able to adapt certain special

devices to their peculiar needs. It is also essential to have connected with every juvenile court a competent medical examiner with the training of a modern psychologist to study every young person who appears before the judge, in order to help in selecting the best course of training in each case; but this is true also of any other kind of school. In general the same preparation in psychology and principles of pedagogy is needed as that given in our best normal schools. But a period of residence and teaching in a reform school is necessary as an apprenticeship. The fact has been in the past that almost the only schools which had a full equipment for physical and manual training, with preparation for industrial skill and habits, were the reform schools and reformatories. Boys were compelled to commit crimes in order to get the education they most needed. The contrast between their behavior in an ordinary book and slate-pencil school and that in a good reform school proved the superior adaptation of the reform school curriculum and methods. Such a contrast could not continue. When the historian of education comes to pass judgment on the evolution of school methods of the nineteenth century, he will probably do justice to the part played by reformatory methods in improving the ordinary public school equipment and conduct. At the same time, especially since 1876, the ideas of Pestalozzi and Froebel, through kindergarten and manual training schools, have been carried over into state reformatory institutions, and there found a congenial soil and welcome. For judicial methods of dealing with delinquent children and the educational significance of these methods, see JUVENILE DELINQUENCY.

After more than a century of trial and reflection on experience, the modern mind has about come to this working theory of social necessity and duty: free public schools for all; compulsory attendance, enforced by suitable rules and agents; public relief when destitution renders parents unable to perform their duty; special schools for abnormal, subnormal, crippled, and delinquent children. Recently the conviction has become clear and decided that this policy, to be effective for the prevention of crime, must be extended to nearly the end of legal minority, — the stormy and perilous passage over the years of adolescence. Just when passion is strongest, conceit is most dangerous, desire for liberty most in need of bit and bridle, and parental control relaxed, society is peculiarly exposed to danger and loss. It is the crime age. The present watchwords of a preventive policy are: vocational schools, vocational guidance, vocational supervision and control, with community provision for recreation and social intercourse under wise supervision. Add to this, financial aid to destitute parents when necessary to make performance of their duty possible.

These are among the essential factors in the most advanced and most adequate theory of crime prevention; and they must all be under the direction of school administration. There is no other organ of society properly equipped for this function. C. R. H.

PENSIONS, TEACHERS' (Retirement Funds). — As commonly used, the term pension signifies an annuity or other periodical payment made to an individual by a government, an institution, a company, a corporation, or an employer of labor, in consideration either of past services, or of the relinquishment of rights, claims, or emoluments. The governments of most civilized countries provide pensions for those disabled in military or naval service, and for their wives and families in the case of death; also for various state officers and public servants upon retirement from active service. European governments frequently grant pensions to artists, authors, inventors, etc., in recognition of eminent achievement, and to their widows and orphans when left in straitened circumstances. The rapid development, during the past quarter of a century in particular, of the system of state industrial insurance and old-age pensions has modified in a marked degree the significance of the pension. Under modern industrial and social conditions the pension has become an economic force of considerable moment. Each generation endeavors to qualify, through training and education, the members of the succeeding generation. These endeavors have produced the modern public school systems. Each generation also tends more and more to assume a social responsibility for the members of the preceding generation as they pass, by age or other cause, beyond the period of productive or effective activity. This social tendency has produced the modern pension systems.

Germany. — The oldest and best developed systems of teachers' pensions are found in various states of the German Empire. Voluntary systems more or less local in character have long existed there, but they have been completely overshadowed by public systems. Until well into the nineteenth century, so far as public provision was made, German public-school teachers were commonly pensioned at the expense of their successors in office. A superannuated teacher was assigned a fraction, usually one third, of the regular income of his former position till death. The new teacher was obliged to get along on the balance of the regular income so long as his predecessor survived. This scheme was replaced in the various states at different

points in the last century by modern public pension systems. Contributions were required from teachers at first in most cases.

In Prussia, which comprises approximately two thirds of the empire, the great body of folk school teachers were pensioned under the old scheme until 1885, when a modern non-contributory pension system in favor of such teachers was introduced throughout the kingdom by a law of that year. This law was closely patterned after the civil-pension act of 1872, as amended in 1882, which applies to teachers in all public normal schools and all public secondary schools for boys in addition to state civil functionaries in general. In 1894 a similar act was passed affecting teachers in public middle schools and girls' secondary schools. These three acts, slightly amended occasionally, are very much alike in their provisions, so far as teachers are immediately affected. None requires contributions from teachers. The chief differences are on the side of public financial support, which varies from purely local through various combinations to purely state support. All pensions of folk school teachers are paid by the state up to 700 marks; the remainder is paid by county mutual associations of local school districts organized by law for that purpose. The laws under consideration apply to all full-time teachers. The regular conditions of eligibility are at least ten years of service and regular retirement by the proper educational authorities on account of permanent disability or after sixty-five years of age. The pension is graded according to teaching income and length of service. Its amount is determined at present by the following formula:

$$\left[\frac{1}{3} + \frac{1}{60}(\text{number of years of service between 10th and 31st}) + \frac{1}{120}(\text{number of years of service between 30th and 41st}) \right] \times [\text{teaching income at retirement}].$$

The range of the pension is thus from one third to three fourths the teaching income at retirement. In general the teaching income consists of regular salary plus free house rent or the equivalent in money. In 1906 there were 10,025 folk school teachers on the public pension roll in Prussia, of whom 8381 were men and 1618 women. The aggregate amount of their pensions was 15,007,764 marks. The average pensions of men and women were 1618 marks and 879 marks, respectively. The pension systems for public school teachers in the smaller states of Germany are similar to those in Prussia. The chief differences are in Bavaria, where contributions from teachers are still required, and where in general pensions are not graded according to salary, but are in absolute amounts.

Pensions have long been provided throughout Germany for widows and orphans of public-

school teachers also, for most teachers in Germany, even in the folk schools, are men. The first agencies were voluntary mutual associations of teachers and special funds from philanthropic sources. Such agencies are still active, but they are now merely supplementary in a very small way to state pension systems. During the greater part of the last century the families of deceased folk school and middle school teachers throughout practically the whole of Prussia were pensioned, rather inadequately, from county pension funds, which all men teachers were required to join. At first the funds were supported almost entirely by the teachers, but the relative amount of public support gradually increased until 1889, when it became complete. Until 1882 the families of deceased normal school and secondary school teachers were pensioned through the agency of a state fund primarily for state servants, to which the teachers were required to contribute. By the terms of a series of laws and orders beginning in 1882 the widows and orphans of teachers in all public folk schools, middle schools, normal schools, and both boys' and girls' secondary schools are now pensioned on essentially the same basis, except for differences in the sources of support. With rare exceptions no contributions are required from teachers. In general a widow's pension is 40 per cent of the pension her husband was drawing or would have been entitled to if retired at the time of his death. The pension of a fatherless child is one fifth of the mother's pension, that of a parentless child is one third of the same amount. The sum of the pensions of a deceased teacher's family may not exceed his own. A pension lapses on the occasion of the marriage or death of the pensioner, and in the case of orphans at the age of eighteen. The present pension systems for widows and orphans in the smaller states were established on the whole much earlier than the fairly recent one in Prussia just described. They are quite similar to the Prussian system. The chief differences are again in Bavaria, and they correspond to those obtaining there in the case of teachers' pensions.

In general it has been customary for university teachers in Germany to retain their positions till death. When disability or old age has overtaken them, they have commonly been released from the duty of lecturing without loss of position or salary. The only loss has been in lecture fees. This plan prevails throughout Prussia to-day. In some of the smaller states, however, regular pensions are provided, graded according to salary and length of service. Pensions are also provided for the widows and orphans of German university teachers, chiefly through the agency of special funds maintained in connection with the several universities. Most of these funds are quite old. They have been supported from donations, state appropriations, and contribu-

tions from teachers. The contributions are in most cases no longer required. In a few universities widows and orphans are pensioned directly from university or state funds. Widows' pensions range from a small sum to about 2000 marks. Orphans' pensions are very much smaller.

France.—Prior to 1853 little was done in France in the way of pensioning teachers. Primary (public school) teachers were required to contribute to savings and insurance funds from which they received on retirement in a lump sum the total accumulated amount and proceeds of their deposits, while secondary and university teachers were required to contribute to a special state fund from which they were regularly pensioned on retirement.

Beginning in 1844 large mutual-aid societies of primary teachers have grown up in France, one of the chief activities of which has been the provision on a contributory basis of small pensions for their members, supplementary to civil pensions. They are voluntary organizations, subject to certain legal regulations. At present there is one such society in each department or county. The pensions provided have averaged only about 50 francs per annum.

In 1853 the present civil-pension law of France was enacted, which included in its provisions essentially all teachers engaged in public education of all grades, primary, secondary, and higher, except members of the teaching orders. All persons within the purview of the law were classified into two divisions, the active group and the sedentary group. The former consisted of functionaries whose duties were considered physically exacting. By the terms of the law all persons affected by it are required to pay contributions in support of the pension system as follows: (1) 5 per cent of the salary received each year, (2) one twelfth of the salary of the first year of service, and (3) one twelfth of each subsequent increase in the annual amount of the same. The general conditions of eligibility are thirty years of service, the attainment of sixty years of age, and, as the law has been interpreted and administered, regular retirement by the minister. For persons with fifteen years of service to their credit in the active group, the conditions are twenty-five years of service, the attainment of the age of fifty-five, and regular retirement. The normal pension is one sixtieth of the average salary during the last six years of service, multiplied by the total number of years of service. But for those serving twenty-five years in the active group, the annual pension is one fiftieth of this average for each year of service. Special provisions were made for pensions in certain cases of disability after a large part of the required service had been completed. The pensions of teachers may not exceed two thirds of the average salary upon which they are computed.

At first all teachers belonged to the sedentary group, but by a law of 1876 regular teachers in public infant schools, lower and higher primary schools, and normal schools were transferred to the active group where they have since remained. Further, this law provided that the pensions of these teachers should be computed on the basis of the six highest annual salaries received, regardless of their time and order. Minimum pensions of 600 francs for men teachers and 500 francs for women were established.

The act of 1853 also provided pensions under given conditions for the widows and orphans of all functionaries included within its purview. Prior to this time little worthy of mention had been done in favor of the widows and orphans of teachers or other officers, and little has been accomplished since apart from the requirements of the law of 1853. Voluntary and philanthropic activities in this field have been meager in comparison with those in Germany. The law of 1853 conferred the right to a pension upon the widow or parentless children of any functionary who was either drawing a retiring pension under that act or had completed the period of service required for eligibility to such a pension at the time of his death, provided the marriage occurred at least six years before the cessation of the husband's functions. The widow's pension is one third the pension the husband was drawing or would have been entitled to if he had retired at the time of death. Whenever from death or other cause the widow's pension is no longer paid to her, it is divided equally among her surviving children under twenty-one years of age. In case a widow stands in the relation of stepmother to surviving orphans the regular pension is shared between the widow and children. By virtue of a decision of the Council of State in 1882 the children of deceased women functionaries have pension rights corresponding to those enjoyed by the orphans of male officers. This is of considerable importance in this connection since women teachers now slightly outnumber the men in the public schools of France, and many of the women are married.

On Jan. 1, 1909, there were 21,051 retired teachers on the civil-pension roll in France. They were receiving an average annual pension of 1220 francs and in the aggregate an annual sum of about 25,685,000 francs. About 18,966 of these teachers had been retired from the field of public primary education with an average pension around 1052 francs. The remainder were secondary and university teachers. On the same date there were 10,158 teachers' widows and orphans in receipt of pensions aggregating 4,306,042 francs per annum.

Great Britain.—The activities of mutual-aid or friendly societies and philanthropic agencies in pensioning public school teachers

in Great Britain have been almost negligible. A limited number of pensions are paid under certain conditions to retired teachers in destitute circumstances from the Benevolent and Orphan Fund maintained by the National Union of Teachers. A few pension annuities are purchased by teachers on favorable terms through a pension fund maintained by the Teachers' Provident Society, affiliated with the National Union.

Long before pensions for teachers were established by direct legislation in Great Britain they were provided on a small scale by the Committee of Council on Education established in 1839 for the purpose of superintending the expenditure of funds voted by Parliament in aid of public education. These pensions were for the purpose of relieving the schools of incapacitated teachers. Little was accomplished until 1875, when the pension system was revived after a suspension of thirteen years by joint action of the two Committees of Council on Education for England and Scotland. In 1898, when the present pension law in favor of public school teachers was passed, there were in effect in England and Wales 219 pensions of the Committee of Council of 30 pounds per annum, 668 pensions of 25 pounds, and 732 of 20 pounds. The total expenditure for the year was roughly 36,000 pounds. The total expenditure in Scotland during the same year was approximately 5400 pounds. In 1906 the pension system under consideration was discontinued in England and Wales.

In 1898 Parliament passed the Elementary School Teachers (Superannuation) Act in accordance with which certificated elementary teachers have since been pensioned in England and Wales and until 1912 in Scotland. The act requires all certificated teachers while serving in public elementary schools to contribute to a deferred annuity fund at minimum rates of three pounds per year for men and two pounds for women. The rates of contribution in 1911, fixed by the Treasury under the act, were three pounds ten shillings for men and for women two pounds eight shillings in England and two pounds in Scotland. On attaining the age of sixty-five, when his certificate is to expire, every teacher is entitled for the remainder of his life to such annuity from the deferred annuity fund as his contributions have earned in accordance with annuity tables fixed under the act. Further, on attaining the age of sixty-five, if one half the years since certification have been spent as a teacher in public elementary schools, the teacher is entitled to a life-long superannuation pension from the state at the rate of ten shillings for each year of the specified service. If a certificated teacher who has served in public elementary schools for at least ten years and during one half the years that have elapsed since his certification, is found to be perma-

nently incapacitated for the efficient performance of his duties, he is eligible under certain rules to receive a disability pension from the state. A teacher who accepts a disability pension forfeits his right to an annuity from the deferred annuity fund, unless he later reenters the service. In 1909 there were 936 men and 688 women teachers in England and Wales in receipt of superannuation pensions aggregating 33,261 pounds and 18,525 pounds respectively. Also 406 men and 1205 women were drawing disability pensions amounting to 14,606 pounds and 30,306 pounds respectively. The figures for Scotland were about one tenth of these on the whole.

In 1912 the act of 1898 was displaced in Scotland by a new pension scheme formulated under the provisions of the Education (Scotland) Act of 1908. The new scheme includes all teachers in elementary and secondary schools in receipt of Parliamentary grants. It is supported chiefly from public funds. Teachers are assessed four per cent of their salaries annually, but these contributions may be returned in full on application if the teacher withdraws from the service. Ten years of service are required for eligibility to a pension, which amounts to 1½ per cent of the average annual salary throughout the period of service, multiplied by the number of years of service. Teachers may retire at the age of sixty and must retire at sixty-five. Disability pensions may be awarded after ten years of service.

Except in Scotland pensions have never been provided to any material extent for secondary and university teachers. In Scotland such teachers have been pensioned to a considerable extent by the institutions employing them. As just noted, the new pension scheme in Scotland includes secondary teachers.

Widows and orphans of teachers are not pensioned in Great Britain except to a very small extent by a few voluntary organizations.

United States.—Relatively little has been done in the United States in pensioning teachers in comparison with what has been accomplished in European countries. In fact until the end of the nineteenth century the only pensions generally recognized as such in the United States were those paid by the federal government on account of military or naval service. Aside from the provisions made by many municipalities for members of the police and fire departments, pensions for public school teachers have been the first of what ultimately promises to become a complete system of civil service pensions.

According to the sources of the funds and the methods of administration, teachers' pension schemes in the United States may be classified into four principal forms: (1) Private-voluntary; (2) Quasi-public; (3) Semi-public; and (4) Public.

Private-voluntary Systems.—The working of the social law of mutual aid for common

defense and protection has produced a number of voluntary associations of teachers. There are two principal varieties of these associations, — the mutual benefit association for temporary aid and the fraternal insurance society. While the first variety should not, strictly speaking, be classified as a pension scheme, the organization and inherent motive seem to warrant its consideration in this connection. Examples of this variety exist in Baltimore, St. Louis, Cincinnati, Cleveland, Detroit, Chicago, Buffalo, San Francisco, and St. Paul. Through initiation fees, annual dues, and special assessments, these associations aim to pay sick benefits and in some instances funeral expenses. The second and more typical variety of the private voluntary organization seeks through the payment of assessments, proportional to salary, to provide small annuities to superannuated and disabled teachers. Examples are to be found in several of the larger cities of the country, — New York, Boston, Philadelphia, Baltimore, St. Louis, and Cincinnati. Certain of these annuity associations make provision for temporary aid also. In some instances these associations are state-wide in their operation (Connecticut Teachers Annuity Guild; Massachusetts Annuity Guild).

The voluntary aid and annuity societies have reached but a small proportion of the public school teachers, even of the localities or states in which they have existed. The development of schemes of a public nature has removed the chief causes that brought the private voluntary organizations into existence.

Quasi-public Systems. — The fundamental characteristic of this class of schemes is the legislative authorization of the creation of funds through assessments, either voluntary or compulsory, equal to a certain percentage of the teacher's salary; and the administration of the fund by public officials. While there is no direct public appropriation to the fund of the quasi-public schemes, deductions of salary on account of the absence of teachers are frequently added to the salary assessments. Further increments arise through donations and bequests. Many of the existing municipal teachers pension funds are organized in general accordance with this scheme.

Semi-public Systems. — In the semi-public schemes the basis of the fund is an assessment on the salaries of teachers. To this, however, the state adds a definite appropriation either directly or indirectly through the municipality. This appropriation may be in the form of a fixed amount or a specified tax levy. The contemporary development of state and municipal pension schemes is distinctly toward this type. The Wisconsin law of 1911 (ch. 323) establishing a "Teachers Insurance and Retirement Fund" is illustrative of the trend. This law provides a state scheme to be administered by a board of trustees consisting

of the state treasurer, the superintendent of public instruction, and three other members, one of whom must be a woman, to be elected by the members of the fund. Ten cents per capita of the school population of the state is to be annually reserved for the fund from the seven tenths mill state school tax. Teachers must contribute to this fund one per cent of their salaries during the first ten years of service, and two per cent thereafter. Teachers already in service may or may not accept the provisions of the law at their option; but teachers entering the public school service after Sept. 11, 1911, accept the provisions of the law in accepting appointment. Annuities amount to \$12.50 for each year of service, the maximum being \$450. Retirement may be made after twenty-five years of service as a teacher, eighteen of which must have been in the public schools of the state; or, upon permanent physical and mental disability, after eighteen years of service in the public schools of the state. The city of Milwaukee already having a retirement fund, the law does not apply to that city.

The compulsory membership frequently provided in the semi-public and quasi-public schemes has given rise to several judicial determinations of the constitutionality of such a provision. The principal ones of these cases are: *State, ex rel. John L. Ward vs. Franklin Hubbard, et al.*, 12 Ohio Circuit 87, 64 N.E. 109, a case arising in Toledo (O.), wherein it was decided that the compulsory provision of the Ohio law was invalid; and *State, ex rel. Jennison vs. Rogers*, 87 Minn. 130, 58 L.R.A., a somewhat parallel case, arising in Minneapolis under the Minnesota law, resulting in a similar decision. On the other hand, the supreme court of New Jersey, *Allen vs. Passaic Board of Education*, 81 N.J.L. 135, maintained the constitutionality of such a compulsory provision.

Public Systems. — This provides a true pension. There is no assessment. It is intended to operate automatically for all public school teachers. This form of pension system exists in Rhode Island and in Maryland. In the former state, by the act of 1907, teachers sixty-five years of age, having thirty-five years of service, twenty-five years of which have been in the public schools of the state, may be retired and receive from the state an annual pension equal to one half of their annual contractual salary during the last five years before retiring. Such annual pension may not amount to more than five hundred dollars.

Pension funds for public school teachers established on the quasi-public, the semi-public, or the public basis, exist in twenty-three states, — California, Colorado, Connecticut, Delaware, Illinois, Indiana, Kansas, Maryland, Massachusetts, Michigan, Minnesota, New Jersey, New York, Ohio, Oregon, Pennsylvania, Rhode Island, South Carolina, Utah, Ver-

mont, Virginia, and Wisconsin. Some of these schemes are state-wide in application, while others are operative as to individual cities or certain classes of cities. The following list is illustrative of these municipal schemes: San Francisco, Denver, New Haven, Wilmington, Chicago, Indianapolis, New Orleans, Baltimore, Boston, Detroit, Minneapolis, St. Paul, Duluth, Omaha, New York, Albany, Buffalo, Elmira, Rochester, Schenectady, Syracuse, Troy, Yonkers, Cincinnati, Cleveland, Columbia (O.), Portland (Ore.), Philadelphia, Harrisburg, Pittsburgh, Providence, Charleston (S.C.), Salt Lake City, and Milwaukee.

Previous to 1905, no general provisions existed for the pensioning or retirement of the members of the instructional staff of higher institutions of learning in the United States. Certain of the larger universities, such as Harvard and Columbia, maintained a limited system of retiring allowances. A small number of the state universities and colleges sought to accomplish in part the end of a pension system through the establishment of emeritus professorships, the holders of which received a reduced salary in return for merely nominal service. With the establishment of the Carnegie Foundation for the Advancement of Teaching (*q.v.*) a general system of retirement of superannuated teachers came into existence, not only to benefit a large number of American colleges and universities, but also to stimulate public endeavor in behalf of pension funds for teachers in public elementary and secondary schools. PENTATHLON (Gk. *πένταθλον*; Lat. *quinqertium*). — The five contests which made up the greater part of Greek athletic exercises. There were included: (1) *Running* (Stadion or 200 yards, quarter-mile, and long distance, three quarters of a mile to three miles). Races were often run in armor, and over soft sand. (2) *Jumping* on soft earth, often with the aid of grips or dumb-bells (*halteres*). The contestants must alight evenly for the jump to count (3) *Wrestling* and boxing. The bodies of the contestants were naked and oiled, and the contest took place on soft ground. (For further details see the separate articles on these topics.) The *pancratium* (*παικράτιον*) was a mixture of wrestling and boxing, and the contestants could use almost any device to win. (4) *Throwing the discus*, a flat disk of metal, eight to nine inches in diameter. (5) *Hurling the spear* or javelin at a target.

PEOPLE'S INSTITUTE, NEW YORK.

— An organization founded in 1897 by Charles Sprague Smith, formerly professor of languages and literature at Columbia University, for the promotion of better understanding and coöperation between the members of different classes in society and different religions. The promotion of social solidarity and social consciousness was to be the chief aim of the Institute. To this end a series of lectures has been organized to distribute better information on the duties of citizens and the various branches of civic and state government. The following are the chief departments into which the work of the Institute is divided: (1) *People's Church*, meeting every Sunday evening to hold a service, irrespective of creed and based on the fundamentals of religion. (2) *People's Forum* for the discussion of questions of general interest in politics and social legislation. (3) *People's Choral Union* and *People's Symphony Concert Association* to enable those who could not otherwise afford it to hear and study the masterpieces of music. (4) *Dramatic recitals* and performances are also provided

in the same way. Arrangements have been made between the Institute and theater managers by which members of the Institute are enabled to secure tickets at reduced rates. In this way the Institute indirectly acts as censor of plays. Instruction is also given in literature, art, natural science, and philosophy. (5) The People's Club was organized to provide centers for social intercourse and recreation for both men and women. The work of the People's Institute with the exception of this club is carried on at the Cooper Union (*q.v.*).

PEOPLE'S PALACE. — An institution organized in 1887 to afford facilities for recreation and education to the people of the East End of London. Its establishment was made possible by a fund left in 1840 by J. B. Beaumont to promote education and entertainment in the East End. The fund was mismanaged until it was taken in charge by Sir Edmund Hay Currie, who added to it by securing gifts and endowments. Meanwhile *All Sorts and Conditions of Men*, the novel by Sir Walter Besant (*q.v.*), appeared in 1882, and attracted considerable attention to the needs of an almost unknown section of London. His suggestion for the "Palace of Delight" proved of great assistance to Sir Edmund Currie and his associates. Sir Walter, as a trustee of the Palace, took an active part in its work. At the same time the establishment of Polytechnics (*q.v.*) in London afforded good models to be followed on the educational side. Queen's Hall, a large concert hall equipped with an organ, a large stage, and a seating capacity of 4000, was opened by Queen Victoria in May, 1887, as part of the scheme. In October evening classes, workshops, laboratories, gymnasium, refreshment and recreation rooms were opened in temporary buildings. In the first year there was an enrollment in the classes of nearly 5000 students. Membership in the institute with free admission to everything but the classes and swimming bath (opened in 1888) was limited to young people of both sexes between sixteen and twenty-five. A Junior section was soon established for those between thirteen and sixteen. The Palace provided concerts, exhibitions and shows, billiard and social rooms, a reading room and library, and clubrooms. Through the support of the Drapers' Company and the Charity Commissioners, financial responsibility for the provision of education was removed from the trustees of the Palace. A day technical school for boys over thirteen preparing for the mechanical industries was opened in 1888 in new buildings. The educational work of the Palace soon grew to such an extent that it was organized into the East London Technical College, now the East London College, a school of the London University (*q.v.*).

PERCENTAGE. — A topic that began to find place in arithmetic after the invention of decimal fractions. (See **FRACTIONS**.) The idea of percentage is, however, an old one, and many traces are found in the records of Babylon, India, Greece, and Rome, showing that computations were frequently made on the basis of a hundred. The word comes from *per centum*, "by the hundred," and since a hundred is a very natural group unit to take for larger business computations, it is not strange that it should have been used even before the convenient decimal fraction appeared. The common per cent sign (%) is a cursive form derived from $\frac{1}{100}$, for *cento*, which appears in the *per* $\frac{1}{100}$, or *per cento*, of the Italian writers of the fifteenth century. By the seventeenth century the Italians wrote $p \frac{0}{100}$ and when the symbol became international the original meaning was forgotten and merely the sign % was left.

Educationally there is no reason for discussing percentage as a separate topic of arithmetic, save as tradition dictates. The expression 6 % has no other meaning than 0.06; it is merely a different symbol and might just as well be taught in connection with decimal fractions, so far as the theory goes. Since, however, business problems in which per cents arise are generally too advanced for a child who may properly be considering decimals, it is probably better to postpone the use of per cents until these problems are reached. But even then it is not necessary to give an elaborate treatment of the theory of percentage before the application of per cents is introduced. This is now coming to be appreciated in the treatment of percentage, the extensive discussion of the various "cases," as seen in the arithmetics of the second half of the nineteenth century, having been abandoned of late. There is a reason for retaining the term *rate*, and some reason for using *base* as a non-technical term, but there is no educational necessity for retaining *amount* and *difference*, and not much need for the term *percentage* as meaning the product of the base and rate. Whenever the simple equation, merely in the form of $0.06 \text{ of } x = \$12$, becomes familiar in the elementary school, all of these terms, excepting *rate*, will doubtless disappear.

The elaborate applications of percentage as seen in the arithmetics of about 1875 are at present giving place to only a few that are within the grasp of children in the seventh school year. The chief applications are to discount, commission (brokerage), and simple interest.

D. E. S.

PERCEPTION.—This term is used in educational writings in a narrow and technical sense. It is also employed in a broader sense in general psychology and in common parlance. The influence of Herbartian writing is accountable for the narrow technical sense in which the term is used in educational literature. It is contrasted with the term "apperception." While apperception indicates clear active mental processes, "perception" as used in this connection refers to vague and relatively passing mental processes. The two terms "apperception" and "perception" were first used by Leibnitz. The same terms were afterwards used by Herbart, and are used in current German psychological discussions, especially by such writers as Wundt. There is no confusion in the German language between the German word *Perception* and the more general vernacular term *Wahrnehmung*, which is used in German to indicate sense perception. The German word *Perception* is, therefore, always a technical specialized term related to the term "apperception." When the term is brought over into English in the Herbartian psychologies as a term contrasted with apperception, an ambiguity of a very confusing type arises. As used in the English language, the term "perception" does not mean at all a vague and relatively passive form of experience, but it refers to a very active and usually vivid type of experience. The translators of Herbartian terminology would therefore have rendered a distinct service to educational terminology by the use of some word other than the English word "perception" to translate the German word of the same form. Some such term as apprehension or vague recognition would have been very much better. The former is employed in the translation of Wundt's *Outlines of Psychology*.

In the broader and more general sense, the term perception refers to the mental experience which arises whenever one recognizes some object that is presented to the senses. Thus one perceives the table upon which he writes, etc. In this general sense, the word perception is to be contrasted with two other psychological terms which define the limits of perception on two opposite sides. Sensation is the first term to be distinguished from perception. Sensation is the relatively simple experience which one derives from the stimulation of his senses. Thus one has sensations of red or green, but his recognition of a red or green surface is more complex than his mere reception of the sensation of red or green. The recognition of a surface implies the contrasting of the sensations derived from this surface with those that are derived from the general background upon which the surface lies. The percept of a surface always has, in addition to color qualities, certain spatial characteristics. Not only so, but the recognition of the object usually de-

pends upon some earlier experience with the object. They are therefore interpreting factors drawn from past experience which are added to the present sensory qualities. Thus, the recognition of the surface of the table is supplemented by earlier knowledge of what a table is and of its uses and of its value. Perception may therefore be described as a complex of sensations and memory experience. On the other hand, perception is to be distinguished from ideas. Ideas are those experiences which one has in the absence of objects. One has an idea of the friend whom he saw yesterday, or of the book which he read last year, while he may perceive the friend who is now before him or the book which he is actively engaged in reading. Ideas are constantly employed to supplement perceptual processes, but ideas differ from percepts in that they are largely under the control of the mind, while percepts offer a certain resistance to subjective modification. One cannot change at will the recognition which he has of a present object; he can, on the other hand, form a series of ideas all giving to the same object different colors or different positions. As contrasted with ideas, percepts may be described as composed in major part of sensory elements, while ideas are made up entirely of memory elements.

The properties exhibited by percepts are due in part to the elements which enter into the percepts, and in part to the process of combination by which these elements are united with each other. Thus, a visual percept is dependent for certain of its attributes upon the visual sensations of which it is composed, but these visual sensations are arranged in an orderly fashion, and are fused (see *Fusion*) with tactual sensations and motor sensations and memory factors. The orderly arrangement of all of these sensations gives rise to the spatial, temporal, and other characteristics of the percept. Form and size are therefore the products of perceptual fusion, and cannot be reduced to any simple sensory factors. In the same fashion, the unity which a percept exhibits is not dependent upon any of the single sensations which enter into it, but rather upon the perceptual process itself. A chair or table is made up of different parts, but all of these different parts are recognized as belonging together. This unity of the experience can be explained only by recognizing the fact that in all human treatment of such complex articles, there is a unity of reaction and adjustment which is paralleled by the unity of mental recognition. Finally, all percepts have position in time, and the time series, like the space series, is the product of the complex process of perception.

The processes of perceptual fusion are so immediate in their character that it has often been assumed that no education of these processes is necessary. The ideational processes, which move more slowly, have been observed

by students of mental development, and the training of these ideational processes, as, for example, in the various forms of memory, has always been recognized as a part of education. When a person fuses his tactual and visual sensations with each other in the formation of a percept, there is no such obvious step from the one group of elements to the other as there is in a series of ideas, and no such evident necessity of assistance from a teacher who can guide the process. For a long time, the school held itself entirely free from responsibility for training the recognition of space, time, and the unity of objects. Experience has shown, however, that children cannot learn fully and accurately to recognize form, size, time, and unity, without some well-directed exercises which aim to train the powers of perception. There is, therefore, at the present time, a strong tendency to introduce into the school program special exercises in sensory training. The above discussion makes it clear that it is not the senses which are trained in this case, but rather the fusion processes which combine sensory experience.

Another reason for the earlier omission of perceptual training is to be found in the fact that certain experiences such as those of space have been reduced in the form of geometry to a system of ideas rather than to a direct form of training of the visual perception. For this reason, a new type of geometry is needed in the lower schools which shall give training in the recognition of space without reducing this experience to abstract ideas. In drawing and in æsthetic training much has been done to improve the powers of perception and the ability of students to discriminate between those forms which are symmetrical and beautiful and those which are irregular. This type of training cultivates space perception as contrasted with Euclidian geometry, which deals with logical comparison.

The importance of the recognition of perceptual processes as significant to the teacher goes very much further than the introduction of the special exercises above described. The necessity of a psychological analysis of all mental processes becomes increasingly obvious as one studies the various forms of perceptual fusion. Fusion is significant because it is not explicitly distinguished by the mind from the elements that are united with each other. It is a kind of involuntary and unrecognized mental development. As soon as teachers begin to note this type of perceptual activity as of importance in mental development, a whole field of psychological investigation is opened up which would be entirely overlooked if one recognizes only the mental processes of an ideational type. PERIOD, LESSON.—See SCHOOL MANAGEMENT.

PERIOD OF STUDY.—The fundamental importance of the problems connected with the period of study both for hygiene and for efficient school work is now recognized, but they are, for the most part, unsolved. We do not know, for example, whether, other conditions being the same, it is better for the health of children and the habits developed to have all the school work done in one session or in two. We do not know whether for the majority of children under usual conditions it is better to have school work done in the morning or in the afternoon, or whether there are two types among children as suggested by the experiments of Krapelin, those who do better work in the morning on the one hand, and those who do better work in the afternoon on the other. Experiments by Lay with a group of children learning nonsense syllables showed that every child retained what was learned better when the study was in the afternoon than when it was in the morning; but fatigue, on the other hand, seems to be greater in the afternoon. Thus, in regard to the many points, we have no adequate evidence as to the best conditions. Significant results have come from many experimental studies, but as regards the length and distribution of the period of study during the school day, the best conclusions that can be given at present are tentative. Putting these briefly and dogmatically on the basis of the studies of work and fatigue, and upon the results of school practice in different countries, the following norms seem wise:—

(1) The length of the school day should vary with the age of the children, and the kind of work done. For the kindergarten and early primary grades one session of three hours is a maximum unless a large part of the work consists of play and is out of doors. In the higher grades and in the high school a four-hour session, or two sessions with a total of five hours, or where much of the work consists of manual training, gymnastics, or the like, six hours, should be a maximum. (2) The problem of one session or two is relative to many conditions. One session a day seems preferable where local conditions favor. (3) There should be no prescribed home study in the lower grades; in the higher grades and in the high school the amount required should not exceed one hour, unless there is only one session not exceeding four hours. (4) The recitation period should not exceed fifteen to twenty minutes for children between six and nine; twenty-five to thirty minutes for children from nine to twelve; thirty-five to forty

minutes for children from twelve to fourteen; forty to forty-five minutes for older children.

(5) Recesses of from five to fifteen minutes in length should follow each period of study, the length of the period being determined by the character of the preceding work, the time of the day, the sequence of subjects, and the like. The total time for recesses for a five-hour period should not be less than that required in Berlin; namely, sixty minutes. The amount of time devoted to recess in this country is usually very inadequate. More time for recess and a better pace of work in most schools would not only favor health but produce more satisfactory results.

Hygiene and pedagogy are quite in accord, and for really efficient school work in most of the schools in this country an entire revision of the program with regard to what is known concerning fatigue and the optimum conditions for intellectual work is desirable. In order to determine the proper length and distribution of the work, many factors are to be considered, — the age of the pupils, the climate, the season of the year, the kind of work done, the home conditions, the sequence of subjects, the work required, the character of the teachers, and the hygienic conditions of the schoolroom.

PERKINS, GEORGE ROBERT (1812-1876). — Author of mathematical textbooks; studied privately mathematics and civil engineering. He taught at Clinton, N. Y. (1831-1838); was principal of the Utica High School (1838-1844); instructor in the Albany Normal School (1844-1848), and succeeded David P. Page (*q.v.*) as principal of that institution (1848-1852). His publications include *Higher Arithmetic* (1841), *Treatise on Algebra* (1841), *Elements of Algebra* (1844), *Elements of Geometry* (1847), *Trigonometry and Surveying* (1851), and *Plane and Solid Geometry* (1854). He also published many scientific articles.

PERMANENT SCHOOL FUND. — See SCHOOL FUNDS.

PEROTTI, NICCOLO (1430-1480). — Italian ecclesiastic and humanist, born at Sassoferrato of poor parentage. At the age of fourteen he became a pupil of Vittorino da Feltré (*q.v.*). Later he is found in the household of William Gray, later, Bishop of Ely, who studied under Guarino. With him he went to Rome and was placed in the household of Bessarion, whose secretary he became. Living at Bologna he studied theology and Greek, and taught rhetoric and poetry there in 1451. He attracted attention when Pope Nicholas requested him to translate Polybius, a work executed with more elegance than correctness. In 1458 Pope Pius II made him Bishop of Siponto. Perotti was frequently employed as Papal legate, but spent the greater part of his time in Rome engaged in literary activity. The latter part of his life he spent in his native town.

While Perotti was very productive, only a few of his works have been printed. His main interest was in rhetoric and eloquence. The *Metrica* (1453) was the earliest modern work on Latin prosody. His *Rudimenta Grammatices* (1468) was the best known and most widely used of his works. Erasmus calls it the "most complete manual extant in his day." It was the archetype of all later grammars with the familiar arrangement of accidence, syntax, and prosody. Grammar he defines as *ars recte loquendi recteque scribendi scriptorum et poetarum lectionibus observata*. The *Cornuopie sive Latine Lingue Commentariorum Opus* was a collection of some of Perotti's works edited by his nephew, Pirro, and contained in later editions commentaries on Martial, Pliny's preface, Varro, Sextus Pompeius, and Nonius Marcellus. Perotti was an ardent student of Greek, and besides Polybius he also translated Epictetus and Plutarch (*On the Fortune of the Romans*). His *De Puerorum Eruditione*, which would have been valuable as from a pupil of Vittorino, has either been lost or was never printed.

PERSIAN EDUCATION. — In the history of education Persia commands attention both as having been one of the great nations of antiquity and as having possessed in early times an educational policy that engaged the consideration of advanced thinkers, like Herodotus, Xenophor, Strabo, and others, in ancient Greece. The intellectual achievements of the people, moreover, during their long history have been such as to entitle the land to a high rank among the Asiatic nations of the

past; and there is still some hope that under its constitutional government, as framed in 1906-1909, the country may in a measure be enabled to emulate some of the achievements of days gone by.

Historical Outline. — Of chief interest historically to the student of education is the older period of Persia's development, or that during the thousand and more years of her greatest power; in other words, the period from the seventh century B.C. to the seventh century A.D. This was the long era covered by the Median and Persian empires down to the invasion of Alexander the Great, and followed by the dominion of the successive rulers of the Parthian and Sasanian Kingdoms. During most of this early age Persia was under the influence of the religion of Zoroaster, the prophet of ancient Iran, who was born at least as early as 660 B.C., and whose faith and teachings were destined to have an educational bearing upon the general condition of the people. This older creed, whose ethical principle of the warfare between Ormazd and Ahriman proved a potent factor in energizing the people, was supplanted and almost wholly driven out by Mohammedanism when the Arab conquest of Persia took place in 650 A.D. From that date onward the country in general shared in the educational as well as the political fate of the adjacent lands that were brought under the sway of Islam. Yet Persia always maintained a certain freedom of thought and independence of judgment that redounded to her intellectual advancement during the succeeding centuries of Moslem rule. In fact many of the products of Oriental learning during the Middle Ages which Europe attributes to the Arabs are not Arab, except in language, but are in reality the work of Persians by birth or extraction (cf. Browne, *Literary History of Persia*, 1. 251-278, London, 1902). A recognition of this truth should play a part in any estimate of Persia's development in later times as well as in any forecast regarding the possibilities of the country when the land is brought into more direct contact with the West and with Occidental modes of thought.

Educational Views and Aims — From the remotest age the aim of education in Persia, as elsewhere, was to train children in such a manner as to make them useful members of the community in whatever state of life they may have been born. A certain amount of religious instruction was regarded as a paramount necessity for the attainment of this end, as is implied in the *Avesta* (Vend. 4. 44-45, Yasna 62. 5, Yasht 13. 134; tr. Darmesteter and Mills in *Sacred Books of the East*, vols. 4, 23, and 31, Oxford, 1880 (2d ed., 1895), 1883, 1887). Among the qualities most highly prized and extolled in that sacred book is the gift of wisdom and knowledge; this is spoken of both as natural wisdom and as acquired — Av. *asna khratu*, "inborn wisdom,"

and *gaoshō-srūta khratu*, "ear-heard wisdom." A special section of the Avestan code, but one unfortunately lost ages ago, was devoted to "the teaching of children by a guardian or father, and the mode of his teaching," and also to "the association of priestly instructor and pupil," as shown by this very quotation from an analysis of the missing part found in the *Dinkart* (8 22. 2; 8 37. 4, tr. West, *Pahlavi Texts*, in *S.B.E.* 37. 77, 114). The loss, in fact, of much of the *Avesta* in its original compass makes it difficult to surmise how broad may have been the vision or how comprehensive the educational aim in those ancient days. If again we may judge from the summary in the *Dinkart* just referred to there was imparted, besides religious instruction, something of science, as it was then known, and likewise of secular knowledge. Further support for this view is to be found in the occurrence in Pahlavi literature of quotations of that nature from missing portions of the *Avesta*, and in some of the old material used in Pahlavi works, like the *Bundahishn*, which is based on the *Avesta* (cf. West, *Pahlavi Texts Translated*, in *S.B.E.* 5, p. xxiv). It is at this point that some outside help may be called in from the classic authors, like Herodotus, Plato, Xenophon, and the rest quoted below, to contribute further information at least regarding the general conditions prevailing in Achæmenian, if not Median, times. In this connection it may be added that, although opinions differ concerning the weight to be given to Xenophon's *Cyropædia* as a source, there are not wanting sound critics who regard that work as thoroughly trustworthy in its representation of Persian conditions, even though it be tinged in color by Greek ideals. For the Parthian period (250 B.C.-226 A.D.), or the darker age that followed the invasion of Alexander, there is a scantiness in material to show the educational attitude of that epoch. For the Sasanian age (226 A.D.-650), on the other hand, there is abundant evidence to prove that learning was valued at its true worth and was liberally fostered. To cite an example in addition to the other quotations given below, the *Dinkart* says, "Education is the life of mankind," and "Men ought to raise themselves to illustrious positions by education (which enables them) to read and write" (see tr. by Peshotan Sanjana, and Darab Sanjana, vol. 12, p. 29 and vol. 9, p. 585). After the Mohammedan conquest, although an Arab infusion came into the Persian speech, and the religion of the Koran superseded that of the *Avesta*, it was the Persians, nevertheless, who taught their vanquishers the value of learning, and, by imparting their own literary gifts to the Moslems, created a golden age of letters for Islam in the eighth and ninth centuries (cf. Browne, *Literary History of Persia*, 1. 251-278). The general attitude toward education in the thirteenth century, as well as

later, may be gathered from the fact that the celebrated Persian poet and moralist Sa'di who died in 1291 A.D., devotes to the effects of education a part of one of the chapters (ch. 7) in his well-known work, the *Gulistan* (tr. Eastwick, 2d ed., London, 1880). The existence of Persian ideals to-day regarding education, despite the obstacles in the way of their fulfillment, is illustrated by the presence of two articles (18 and 19) in the supplementary fundamental laws adopted as a part of the national constitution that was framed in 1907. The first of these articles recognized entire freedom in the matter of "the acquisition and study of all sciences, arts, and crafts," except such as may be forbidden by ecclesiastical law; the second exacted that "the foundation of schools at the expense of the government and the nation, and compulsory instruction, must be regulated by the Ministry of Sciences and Arts, and all schools and colleges must be under the supreme control and supervision of that Ministry."

Teacher and Pupil in Antiquity. — From the earliest times the priestly class naturally occupied the foremost position in the matter of teaching. In the *Avesta* a special religious atmosphere is associated with the oft-recurring words for pupil and teacher, which are *athrya*, "(priestly) learner" and *athrapati*, "master of (priestly) learning." The relation between disciple and master was an intimate one, and even a devoted one, as we know from Yasht 10. 116, where a list of sacred ties is given, and this particular bond is rated as "seventyfold" in the scale of a hundred, being surpassed only by that between father-in-law and son-in-law, between two brothers, and between father and son. At this point we may likewise recall the import of the quotation given above from the lost Avestan *Husparam Nask*, bearing upon "the association of priestly instructor and pupil, and their meritoriousness together" (Dk. 8. 37. 4). A recognition of the importance of this bond, moreover, may partly account for traditions ascribing to Zoroaster himself a special teacher or teachers (see Jackson, *Zoroaster*, pp. 29-30, and compare the Avestan fragment given by Darmesteter, *Le Zend-Avesta*, 3. 151 and *S.B.E.* (2 ed.) 4.371). It is not without interest to add that the name of an ancient teacher appears to be mentioned in a list of sainted names found in the Avestan canon, but we unfortunately know nothing more about him; the passage (Yasht 13. 105) reads, "we worship the guardian spirit of Manthravaka, son of Saimuzhi, the master of (priestly) learning and master of the conference." His son Vahmaedhata is likewise named (Yasht. 13. 115). An original Avestan fragment relating to the duties of a priestly student and his preceptor has been preserved, but the text is in so corrupt a condition that the interpretation of it is not wholly clear (see Erpatistan, 16-18, tr. Darmesteter, *Le Zend-*

Avesta, 3. 85, and *S.B.E.* 2 ed., 4. 311-315). The passage in question runs as follows:—

"How long a time, of a year's length, shall a student go to a master of spiritual learning? For a period of three springtides (i.e. years) he shall gird himself with the Holy Wisdom. If within a half of this period, when he is reciting, he makes a mistake or leaves out something, he shall go to a second teacher, to a third, even to a fourth. If we see that he knows his text within the half of this period, he must recite it and not leave out anything afterwards" (see also Bartholomae, *Altiranisches Wörterbuch*, col. 132, s.v. *antara*, Strassburg, 1904). In the light of such a passage it is easy to understand the importance attached to religious and moral instruction in Sasanian days as shown by the admonitions of the sage Buzurgmihr, prime-minister to Chosroes I, surnamed Anushirwān the Just (550 A.D.) in his *Pandnamak*, or "Book of Advice," he says:—

"(36) Education makes man noble, good habits endow him with a virtuous disposition, education is a corrector of man, good deeds the guardian of his soul (126) A man should spend one out of the three parts of every day and night in getting religious training and in asking sensible questions of pious men. (142) Hence all men, except blind, dumb, and disabled persons, ought to take as much trouble as they can in this world, and to educate themselves in a theological seminary. . . .

(143) It is the duty of parents to instruct their children, before they attain their fifteenth year, to do many of the good deeds (duly enumerated). For those parents that give a certain amount of education of this kind to their children obtain their recompense from whatever good deeds their children do; but those that do not give it draw upon their own heads whatever iniquities their children, devoid of the strength it affords, commit" (see the Pahlavi *Pandnamak-i Vajorg-Mitro*, ed. and tr. by Peshnutan Dastur Behrang Sanjana, under the title *Ganyeshayagan*, pp. 11, 21, 25).

From expressions like the above regarding parents, children, and teachers, we can appreciate the claim made in the first century B.C. by the Greek writer Nicolaus Damascenus (fragm. 67) to the effect that "Cyrus was versed in the wisdom of the Magi, in which he was educated; he was instructed in righteousness and truthfulness, and in certain customs of his native country, which exist for prominent men among the Persians." In keeping with this is the statement of Xenophon that "boys attending school pass their time in learning justice" (*Cyrop.* 1. 2. 6). Of a like tenor is the information given by Strabo to the effect that the youths are given "the most virtuous instructors, who interweave useful stories into their narratives, and relate, sometimes with and sometimes without music, the deeds of their gods and celebrated men" (Strabo, 15. 3. 19, Cas. p. 733).

Age of Instruction. — As to the age at which the child's education was to be begun, there appears to have been a natural degree of latitude between the ages of five and seven, the latter being certainly the time when formal instruction was commenced. Up to the age

of five, according to Herodotus (1. 136), the boy did not enter his father's presence, but was brought up among the women. The same age is mentioned by Strabo (15. 3. 18, Cas. p. 733), although Valerius Maximus (2. 6) gives seven. The part played by eunuchs as well as the women in the child's bringing up is noted by Plato, *Leges*, 3, 695 A, 694 D, and the Platonic *Alcibiades*, I, 121 D. At the Sasanian court, according to Firdausi (tr. Mohl, 5. 341), a special priest was in charge of the youthful Shapur II (309-379 A.D.) until he reached the age of five; and similar care was taken of the precocious Bahram Gur (420-438 A.D.) until the end of his fourth year (*op. cit.*, 5. 400). From five until seven years the child was under the father's tutelage, according to the Pahlavi treatise *Shayast la-Shayast*, 5. 1 (tr. West, *S.B.E.* 5. 290). In general the systematic course of education began when the child was seven years old. This may be inferred from a passage in the *Avesta* (Vd. 15. 45), which says that "the care (*thrāthra*) of the child is for seven years"; as well as from the *Dinkart* (tr. Sanjana, vol. 4, p. 263), which regards the child's power of reasoning as developed at seven, and the child as then responsible to being held accountable by its parents; and a similar idea is found in the *Shayast la-Shayast* (5. 1-2) and elsewhere. (Cf. also Platonic *Alcibiades*, I, 121 D.) This continued from the seventh to the fifteenth year. The age of majority was reached at fifteen when the young man, as did the maiden, took upon himself the religious and other obligations belonging to maturity as recorded in the *Avesta* and in the Pahlavi books (see *Avesta*, Vd 18. 54; Vd 14. 15; Yt. 8. 3-14; Ys 9. 5; H. N. (Yt. 22 9); Pahlavi, Syls. 5. 25; Zsp. 20. 1; Dk. 7. 10, 17 (tr. West, *S.B.E.* 47. 151, 115); Pandnamak, 143, tr. Sanjana, p. 25). Such was the case with the young prince Ardashir Babagan, the founder of the Sasanian dynasty (cf. Karnamak-i Artakhshir, ed. and tr. Antia, p. 6, Bombay, 1900; also ed. and tr. Darab Sanjana, p. 5, Bombay, 1896); but the exceptionally gifted Bahram Gur, on the other hand, appears to have completed his studies at twelve (see Firdausi, tr. Mohl, 5. 402). These natural differences in point of years may well account for the varying ages given by the classical authors who refer to the education of the Persian princes and nobles, especially their military and physical training. Thus, Xenophon (*Cyrop.* 1. 2. 8) makes the earlier stages of instruction continue to the sixteenth or seventeenth year; Herodotus (1. 136) to the twentieth; and Strabo (15. 3. 18) up to the twenty-fourth year. According to the Platonic *Alcibiades* I, 121 D, the age of fourteen was the time when Persian princes were given out to special royal tutors for advanced training.

Study, Recreation, and Physical Exercise — Persians, like their descendants to-day, were

early risers, and all instruction appears to have begun at an early hour. The *Avesta* (Vd 18. 23-26) insists upon the virtue of being out of bed by cockerow; and the Pahlavi tractate containing the advice given by Atūrpāt to his son bids the youth, "rise early that you may be able to continue your work" (*Andarj-i Aturpat-i Maraspandan*, 98, ed and tr. Sanjana, p. 7). The ideal distribution of the day for the Zoroastrian, especially the peasant, is given by Buzurgmihr (Pandnamak, 126 tr. Sanjana, p. 21), and this arrangement assigned one third of every day to religious thought and pious activity, the second third to cultivating the soil, and the remainder to eating, recreation, and sleep. Judging from an Avestan allusion to the duties of a priest (Vd 18. 5-6), the true cleric was supposed to study day and night (lit. "through the whole night"). In the case of the warrior class and the nobles, early rising was insisted upon, and much of the training consisted in physical exercise. Xenophon (*Cyrop.* 1. 2. 4; 1. 2. 10) related that the boys, like the men, were accustomed to rise early and to appear in the market place "at daybreak." Strabo (15. 3. 18, C. p. 733) adds, "the youths are called to rise before dawn, at the sound of brazen instruments, and assemble in one spot as if for arming themselves, or for the chase; they are arranged in companies of fifty, to each of which one of the king's sons or the son of a satrap is appointed as leader, who runs, followed at command by the others, an appointed distance of thirty or forty stadia. They require them also to give an account of each lesson, when they practice loud speaking, and exercise the breath and lungs." Both Strabo and Xenophon elaborate upon the athletic and martial aspect of the instruction, and no one can overlook the oft-quoted statement of Herodotus (1. 136) that the Persians taught their boys "three things only: to ride, to shoot, and to speak the truth." This was undoubtedly true, because the Persians from the days of Zoroaster onward have been advocates in practice as well as theory of the doctrine *mens sana in corpore sano*; and riding horseback, hunting, archery, javelin throwing, swimming, and polo were regarded not merely as manly sports, but as an essential part of education (see Modi, *Education among the Ancient Iranians*, pp. 1-40).

Scope of Instruction in Early Times. — As already indicated, the general scope of the education in early times was both mental and physical. The former preponderated in priestly education, the latter in the training of the knights and nobles; the training of the third estate, as intimated above, must have been mainly practical in its bearings. Owing to the loss of portions of the *Avesta*, previously referred to, no definite details have been preserved to show the general method of instruction in vogue; but there is undoubtedly much

truth in the picture of Persian education drawn by Xenophon (*Cyrop.* 1. 2. 2-13), even if the likeness be an idealized one.

In substance, according to Xenophon, the Persians insisted upon positive precepts and examples in their teaching rather than upon negative commands, and they believed in educating numbers together in common. To this end they had "an assembly place (*dyopa*), called the Free, where the royal palace and other official residences were built," and from which all business was excluded as interfering with the instruction. This "assembly place" (which corresponds to the "Maidan" in modern Persian cities) was divided into four parts, one for boys, one for youths, another for men of age, and still another for those past military service. Over each of the four divisions, which again were subdivided into twelve, a presiding officer was placed, old men being in charge of the children, and men of maturity directing the youths. The children were taught justice and its administration, obedience, and self-control, together with training in archery, and throwing the javelin. This continued until they reached the age of sixteen or seventeen and entered the class of young men. Upon them now developed the more serious activities, largely military in character, such as standing on guard, practice in the use of weapons, and taking part in the royal hunt. After ten years, or at the age of twenty-five or twenty-six they were accounted as full-grown men.¹

From the Middle Ages to the Present. — As a direct consequence of the Mohammedan conquest, which occurred in the seventh century A. D. and introduced a different era in Iran's history, Persian education underwent a change in regard to its religious basis, since the Moslem faith was then substituted for Zoroastrianism and has ever since remained

as the general creed of Iran. This departure, however, did not interfere with the production of great works on history and science, standard for their day and times. As witness of this truth may be cited the learned annalist Tabari, in the ninth century, the philosopher-physician Ibn Sina, a contemporary of the great Khivan scholar al-Biruni, at the end of the tenth, several renowned authorities among the number of so-called Arab geographers from the tenth to the twelfth century, Omar Khayyam, the algebraist and astronomer-poet, early in the thirteenth, not to mention the long line of Persian poets down to the fifteenth century. Each dynasty had some intellectual product to mark its fame. Noteworthy in regard to the culture he inspired was the reign of Shah Abbas the Great (1587-1629), not only a great ruler and administrator, but also a noble patron of art and of learning, so that the renown of his reign has rarely been surpassed in the history of Persia's glory, and has never since been even approached.

Education unfortunately has been allowed steadily to decline, and although the traditional native instruction is still in the hands of the Moslem priests in schools attached to the mosques, general learning has fallen more and more into decay. Illiteracy is largely the rule to-day among the people outside of the cities, except where the introduction of Western education may have forced a rise of standard in the local system. Chief among the centers that serve as nuclei for Occidental education are the mission institutions at Urumiah, Tabriz, Rasht, Hamadan, Isfahan, Shiraz, Yazd, and Mashad. In Teheran there are a number of madrasahs, or native colleges, and also several institutions on royal foundations, including the Shah's college, in which European instructors are employed as well as native teachers. Best attended, perhaps, among the Christian institutions of Teheran is the American School for Boys (cf. Jackson, *Persia Past and Present*, p. 423; and on mission and native education consult Wilson, *Persian Life and Customs*, pp. 187-188, New York, 1895; Wishard, *Twenty Years in Persia*, pp. 238-242, New York, 1908). A wholesome sign for Persia's future possibilities, if given an opportunity, may be seen in the establishment of a number of newspapers after the Constitution came in, and also in the rapid multiplication of printing presses.

From the historic standpoint it is not without importance to add that the relatively few members of the ancient Zoroastrian faith, numbering now about eleven thousand, who have managed to exist in the face of religious persecution and civic disabilities, are still a potent moral factor in Persia, and have succeeded in keeping up some sort of educational standard in their relatively outcast community. In maintaining this they have been liberally aided by their coreligionists, the

¹ Twenty-six years was also the age when the Sasanian King Shapur II is regarded as having reached his sovereign dignity according to Firdausi (tr. Mohl, 5. 342). This age corresponds in effect with the twenty-fourth year mentioned by Strabo (15. 3. 18, C. p. 733).

There are passages in the classics which show that the children of noble families were sent to court to enjoy the advantages given by royal education (see Xenophon, *Cyrop.* 8. 6. 10; *Anab.* 1. 9. 3; Procopius, *De Bello Persico*, 1. 23), and reference has been made above to the "royal tutors," four in number, appointed respectively as instructors to the princes in religion and kingly duties, truthfulness, self-restraint, and bravery (see Platonic *Alibiades*, I, 121 D-122 A; and Clemens Alexandrinus, *Pedag.* 1. 7). This statement may be compared with the fact that as a youth the Sasanian King Ardashir Babagan was "instructed in reading, writing, riding, and other arts, and became so proficient that his fame spread all over Fars" (*Karnamak*, 2. 4-5, ed. and tr. Antia, p. 6, also ed. and tr. Sanjani, p. 6). A further idea of the general regimen employed in the education of princes in Sasanian times may be gathered from the training of Bahram Gur (420-438 A.D.), who was sent to Arabia for his earliest education, and from that of Hurmazz IV, in the sixth century, so far as this portrait by Firdausi in his *Shah Namah* may be regarded as accurate (tr. Mohl, 5. 398-405, 6. 424-430).

Parsis of India, who fled from Iran at the time of the Mohammedan invasion, twelve centuries ago, and established themselves most prosperously in the Bombay Presidency, where they themselves maintain flourishing schools that still give broad instruction on Western lines, and also exercise an influence in keeping up the ancient faith (see Jackson, *Persia*, pp. 379-380, 427; Karaka, *History of the Parsis*, 1, 280-332, London, 1884; Menant, *Les Parsis*, pp. 292-332, Paris, 1898).

Female Education Largely Neglected. — The general neglect of female education throughout the history of Persia has been due largely to the Oriental custom of secluding women. Even in ancient Zoroastrian times, so far as can be gathered from the *Avesta*, a girl's education was practically confined to some religious training and to such simple instruction as would make her a dutiful wife and a good mother of the household (cf. *Avesta, Aiwisruthrima Gah*, 4. 9, and the references given by Sanjana, *Position of Zoroastrian Women*, pp. 15-17, Bombay, 1892). A Pahlavi treatise containing admonitions, the *Andar-i Aturpat* (ed. and tr. Peshutan Sanjana, p. 2, Bombay, 1885), includes, it is true, an allusion to the education of one's wife together with one's children, self, and countrymen; but the reference is really to religious instruction (as also is noted by Sanjana, *op. cit.*). As to Mohammedan times, evidence may be adduced in proof of the fact that girls received some instruction by the side of boys. This is shown by the romantic story of Laila and Majnun, or the Persian Romeo and Juliet, whose love began while they were still mere school children, according to the poet Nizami in the twelfth century. (See Atkinson, *Laili u Majnun*, tr., p. 5, London, 1836.) Miniatures portraying this supposed schoolroom scene are found in some of the oldest and most beautiful Persian manuscripts of Nizami's poems, and they might well be consulted by students interested in the history of education. In modern times, little has been done thus far for female education in the native communities, but a good deal has been accomplished in the Christian mission schools, where education for girls is universally given, and indications of progress lend encouragement to the cause, especially as the Persians themselves are now promoting it. (Wishard, *op. cit.*, pp. 240-241, and cf. Ella C. Sykes, *Persia and its People*, p. 197.) A. V. W. J.

PERSONAL EQUATION. — The amount which must be allowed for by a person in making an observation because of the individual character of his reaction time. Originally the term was used by astronomers in connection with the observation of the time of transit of the heavenly bodies. This was done by observing the image of the heavenly body as it crossed parallel lines in the telescopic field, the time being noted simultaneously by counting the beats of a clock. It was found that different observers varied in their results and that the difference was large enough to interfere seriously with the results of the observation. Historically this difficulty led to the reaction time experiment of experimental psychology. E. H. C.

PERSONALITY. — Personality is closely allied with the conceptions of individuality (*q.v.*) and selfhood. (See SELF.) Taken literally, it means the state or quality of being a person. The concept of person arose in connection with Roman law. To be a person was to be a subject of legal rights and responsibilities; that is, of powers and duties capable of enforcement by civil authority. On this view, a corporation or minor civic group, likely a municipality, was a person; slaves were not persons, while minors were persons only vicariously, or through their authorized representatives. As the external traits of this legal view disappeared, an ethical sense developed out of them; a person is the subject of moral rights and duties. Thus Kant said that the moral laws was summed up in the injunctions: Be a Person, and respect others as Persons. A person is an end in and for himself, never a means to anything beyond.

Because of this ethical sense personality is often treated as a "higher" idea than individuality. From another point of view personality is an abstraction compared with individuality. All persons have personality in the same sense; there is nothing distinguishing, nothing concrete about it. Individuality, on the other hand, is always differential; it is something that specifically characterizes each self. Individuality expresses what one uniquely is; personality expresses what one has — a property that one may acquire. In this sense, individuality is deeper than per-

sonality. In earlier days children were classed with slaves as intermediate links between things and persons, save that they differed from slaves in the potentiality of personality. This conception of childhood was embodied in methods of discipline, punishment, and instruction, it being assumed that children had no rights of their own. With the development of the democratic idea, rights of personality were extended to children, and methods of education have accordingly undergone considerable reconstruction. No consistent theory upon this point has, however, as yet, been worked out in practice. J. D.

PERU, EDUCATION IN. — Peru is a republic with an area of 700,000 square miles, including disputed territory, and a population of 4,600,000. The population of Peru is composed of whites, chiefly the descendants of the Spaniards, mestizos or a mixture of Spanish and Indian blood, Indians, Negroes, and a few Orientals. There is almost every degree of civilization, from the barbarous tribes of the montaña to the highly cultured people of Lima, the capital of the Republic, and other large centers. The population for the most part is grouped in centers, but these centers are widely distributed, and means of communication are not good. Geographically, Peru is divided into three sections — *la costa*, *la sierra*, and *la montaña*. The first is a narrow strip extending along the Pacific coast for a distance of some 1200 miles. It is generally arid; but it is pierced by sixty mountain streams which during the ages have left along their banks rich deposits of alluvium now covering an area of 2000 square miles. The *sierra* is the mountainous area, including many fertile valleys, lying between the coast and the *montaña*, which comprises about two thirds of the total area of the country. Only a small portion of it is inhabited. The political divisions of the country are as follows: nineteen departments and three provinces with the organization of a department, 103 provinces, nearly 800 districts, and a large number of sub-districts. The political organization is governed by the constitution, as formed in 1860. The authorities in immediate control of the different subdivisions of the state are, prefect, subprefect, governor, and lieutenant-governor, respectively. These form a political hierarchy responsible to the President of the Republic and his cabinet, in whom all administrative authority is centralized. The Roman Catholic

Church is the only one recognized by law, but as a rule other denominations are not molested.

Historical. — The Spanish adventurers whose conquest of Peru with its ruthless spoliation of the Incas forms one of the most thrilling episodes in the history of the Western continent, were accompanied in this region, as elsewhere, by church dignitaries and prelates who established the authority and ceremonial of the Roman Catholic Church as fast as permanent settlements were effected, organized schools, and upon the ruins of the ancient civilization built up a new aristocracy, tyrannical, luxurious, but, in a sense, cultured. While this alien power was strengthening itself, a few priests with true missionary zeal labored to convert the humble natives, and opened mission schools which imparted to them a curious mixture of letters and religious dogma. The Jesuits controlled many colleges in the colony from the sixteenth until their expulsion in the eighteenth century. The University of San Marcos, the oldest in the Western continent, was established in Lima under Dominican auspices, by Papal Bull of 1571 and confirmed by royal decree the following year; that of Cuzco in like manner in 1692. Around these institutions grew up preparatory schools, or colleges, intended mainly for the training of religious novitiates and teachers. The natives that came into direct contact with the Spaniards gradually assumed their social ideas and mental habits. Thus modern Peru has inherited from the colonial period the framework of a centralized scholastic system and the culture ideals of an aristocratic order.

In 1821 Peru declared its independence, and in the organization of the republican government due regard was paid to education. In 1822 a normal school was established in Lima on the Lancasterian plan, and in 1823 a central office of education was created. This early agitation had, however, little effect outside of Lima, where in 1833 four schools were established for each sex. Like the earlier normal school they showed the influence of the Lancasterian system. The course of study comprised reading, writing, arithmetic, grammar, and religion, with instruction in sewing for the girls. For half a century the history of elementary education in the Republic is little more than a record of official orders and the increase of free schools in the capital. During this period secondary education was represented by the colleges in which pupils were prepared for admission to the universities. The continued interest in higher education was shown by the founding of the universities of Trujillo and Arequipa in 1824 and 1835, respectively. In 1876, under the leadership of President Manuel Pardo, a reform movement was started; but its progress was interrupted by the destructive war between Chile and Peru which raged from 1879 to

1884. The century was near its close before popular education again engaged the attention of the government.

Present System.—In 1896 a special commission, the *Junta Reformadora*, was appointed to deal with the educational problem of the Republic. The outcome of the work of the commission was the law of 1901, which forms the basis of the present system of public instruction. The law provided for a Minister of Public Instruction, Justice, and Worship; in respect to his educational functions he was to be assisted by a Director-General and a Superior Council. The reaction against local independence, which is indicated by the law of 1901, was completed as regards secondary and higher education by an order of September, 1905, transferring their control from the Superior Council to the Minister, and as regards primary education, by the law of December 5, 1905, which bore the signature of José Pardo, who had succeeded his father as President. By this law the control of primary education was centralized in the Minister of Public Instruction, and the inspection of primary schools intrusted to district inspectors subordinate to provincial inspectors, the latter being directly responsible to the Minister.

In 1907 the National Council of Education was reorganized, its membership being fixed as follows: the Minister as presiding officer, the Director-General of Public Education, the Rector of the University of San Carlos at Lima, a delegate elected by each of the faculties of this university, the Director of the National College of Guadalupe, Lima, the director of the men's Normal School, the three directors of the schools of Engineering, Agriculture, and Arts and Trades, respectively, and a delegate named by the private schools. This Council, which works through committees, has the right of initiative in all school matters. As regards primary education, the most important feature of the administrative system is the inspectorate. In accordance with the provisions of the law of December, 1905, a paid inspector of primary schools was placed in each of the 101 provinces of the Republic, while in nearly all the 800 civil districts, unpaid inspectors, subordinate to the former, were appointed.

As the work of organizing public schools went on, the need of expert guidance became more and more evident, and at the beginning of the present administration measures were taken to supply this demand. The newly appointed Minister of Public Instruction, Dr. Manuel V. Villarón, was a man of exceptional ability, familiar with educational movements in the leading countries of the world, and desirous of introducing into Peru the main features of the system of school administration in the United States. At the suggestion of the Minister, the Peruvian government, in May, 1909, secured from the United States a

small number of professionally trained men, for appointment as inspectors of primary instruction, a specialist in commercial education to organize the work in the national college of secondary instruction in Lima, and a specialist in educational administration, to act as adviser to the Minister. Soon after these appointments were made, a change of ministers occurred, but the educational work was not interrupted. In February, 1910, a special commission was appointed under the presidency of Dr. Villarón, for the purpose of preparing a new education law and perfecting the administrative system on the lines already laid down. As indicated by the crude draft of the bill on which the commission is working, they will endeavor to secure, as first essentials, provision for a permanent force of trained teachers, for an inspection corps of high qualifications, and a permanent school fund. The importance of local activity and responsibility in a system of public education is recognized by the commission; but at present these conditions cannot be secured in Peru.

Primary Schools.—Primary instruction is divided into elementary, covering two years, and higher primary, which covers a period of three years. The elementary period is legally obligatory for all children. The higher primary or optional course is provided only in central schools (*centros escolares*) which exist in all the capitals of provinces and in some of the other more important towns. The regulation provides for one school in all plantations, mining settlements, and villages of less than 200 inhabitants; those of more than 200 are entitled to a central school. Unfortunately the funds available are not sufficient to carry out this purpose. The regulations provide for infant schools, or kindergartens, in the capitals of provinces, but so far they have been organized in the larger cities only. In general the pupils are separated according to sex; but mixed schools exist for economic reasons. On account of the prejudices of parents, a mixed school is very rarely coeducational; in most communities the sex that happens to predominate will attend, the other remaining at home, this generally falling to the lot of the girls. Even when both sexes attend, they are seated in different rooms and are instructed separately. Although the school age is from six to twelve for girls and six to fourteen for boys, mixed schools cannot legally receive boys over ten years of age or girls of more than twelve; however, in many "mixed schools" where one sex is crowded out, there are pupils over fifteen years of age. The principals of boys' schools are always men, though women teachers are frequently employed as assistants; only women may have charge of or teach in mixed schools. Outside of the larger cities not much interest has been awakened in the education of girls.

Course of Study.—The course of study for

PERU

the elementary division comprises, besides the three essential branches, nature study and religion (catechism), notions of geography and history of Peru.

The second division continues these subjects and adds Spanish, physics, chemistry, natural history, manual training with inventive geometry and drawing, music, physical exercises and hygiene, notions of agriculture and arboriculture; the moral instruction consists of the Christian dogma and sacred history, and social duties. In the fourth year horticulture and drawing from nature are added to the preceding subjects, and the manual training begins to differentiate according to the sex of pupils, the girls taking up weaving, sewing, embroidering, and laundering, while the boys have elementary work in carpentering, blacksmithing, tailoring, shoemaking, and printing, according to the trades most in demand in the community. In the fifth year, civic education takes the place of moral and religious instruction. It is an overcrowded program and is seldom fully carried out.

Schoolhouses and Supplies.—Public education is not only compulsory, but free; the government provides the schoolhouse and furniture, and, also, free of cost to the pupils of the first two years (the compulsory period), textbooks, pencils, tablets, pens, etc. This liberality, together with the aim of the government to provide a home for each teacher holding a permanent appointment, a gradual increase of salary and a pension after twenty years of service, indicates something of the scope of the reforms recommended by President Pardo in 1905. Owing to the lean years through which the government is now passing, it has not been possible to realize all these purposes.

Teachers, Certificates, Salaries, etc.—Teachers belong to one of three classes according to the manner of appointment, that is, by the provincial inspector, by the prefect of the department from a list of three proposed by such inspectors, or by the minister. The first class of appointment is temporary, the teacher being subject to removal or transfer at the will of the inspector; only the minister can remove or transfer a teacher of the second class; those of the third class receive their appointment as the result of a competitive examination, or on the basis of successful experience, and hold their position for life or until they are retired, unless removed for flagrant misconduct.

There are three grades of teachers' certificates which are secured by examinations conducted by the departmental inspectors. Under present conditions the examinations are of little value, but with the improvements contemplated it is believed they will offer the means of obtaining competent teachers, provided fair salaries are paid. At present these

PERU

are very low, the average annual salary not exceeding \$240. The few graduates from the normal school for men command \$600 a year; graduates from the normal school for women, from \$270 to \$480. The cost of living is about the same as in the United States. According to the law of 1905, teachers who hold their schools by permanent appointment, after serving twenty years may be retired on half pay, provided that during that period they have contributed to the fund 4 per cent of their salary, which must be at least \$25 a month.

For the training of teachers, there are three normal schools: one for each sex in Lima and one for women in Arequipa. These schools have been staffed in the main with foreign teachers and are doing excellent work. They are, however, quite inadequate to supply the annual demand for new teachers, as they do not send out more than forty graduates a year. Consequently the commission advises the maintenance of teachers' institutes in all the departments, as a means of giving professional training to candidates who have met the scholastic requirements for certificates. There are now about 3000 teachers and principals in the public schools, of whom not more than 160 have had a normal course or other professional training, and less than 40 per cent have secured any certificate whatever.

Condition of School Buildings.—The provision of sufficient school buildings suited to the work imposes a heavy tax upon the school income. In 1909 there were nearly 2000 buildings in use, of which 550, valued at \$410,199, belonged to the government. Many of these buildings had been used as prisons or barracks and had been converted into schoolhouses without much alteration. The new buildings constructed in Lima and Callao are models in arrangement and sanitary conditions; but under the straitened financial conditions, progress in this respect has ceased for the present.

Signs of Progress.—In spite of the difficulties of the situation and the many deficiencies to be overcome, there are gratifying signs of progress accomplished since 1905. This is more apparent in the awakened interest in the cause and the aroused ambition of the teachers than in measurable results. The following statistics, however, show advance in important particulars.

	1906	1909
Number of schools	1425	2159
Number of teachers	1557	2909
Number of enrolled pupils	85,000	153,901
Average attendance	73,098	84,408
Number of pupils completing two-year period	8377	11,177
Number of pupils completing five-year course	278	511

PERU

Secondary Education.—The secondary schools of Peru (*colegios*) offer a course of study continuous with that of the primary schools and leading up to the universities. The principal or director of each college reports directly to the Minister of Public Instruction as to the state of his institution. For each college there is a financial committee which prepares the estimates of annual expenditure and exercises a measure of supervision over the disbursement of the funds appropriated. The professors are responsible only for their class instruction. A few of the colleges in Lima and Callao have a permanent staff of foreign teachers and are doing good work; but the prevalent custom of engaging local professional men, lawyers and doctors, to give instruction precludes satisfactory results.

The course of study which is uniform for all the colleges covers four years, and comprises for the first two years the following subjects: Spanish, English or French, general history, geography, arithmetic, science, religion, penmanship, drawing, and music. The science subject for the first year is zoology; for the second, botany. In the third year the science course is extended to include mineralogy and geology, physics and chemistry with laboratory work. The fourth year, philosophy and civics are added, time for these being gained by reducing the other subjects. Pupils enter the colleges at twelve years of age, coming alike from the public primary schools or from preparatory sections of the secondary schools. The overcrowded course is intended for four years, which is evidently too brief a time for the mastery of the severer studies. The total number of colleges is twenty-seven, of which three situated respectively at Cuzco, Trujillo and Ayacucho are for girls only. The others are also open to girls, but few ever seek admission to them on account of the prejudice against coeducation. The number of pupils attending the colleges in September, 1910, was 2787, of whom 1106 were in the primary departments.

Sources of Support.—The sources of support for the secondary schools are government and departmental subsidies, income from properties, and tuition fees. The last-named source yields about 25 per cent of the entire income, which in 1910 amounted to \$340,000, or an average of \$12,592 for each college. The repeated endeavors to establish a permanent school fund have been thus far unsuccessful; the organic law of 1901 provides that 5 per cent of the national revenues, 30 per cent of the departmental revenues, and the proceeds of the duties on liquors shall be devoted to the maintenance of primary schools. But the amounts thus realized have not been sufficient for the service. The total receipts for the successive years 1906 to 1909 were as follows:—

		PER CAPITA OF ENROLLMENT
1906	\$1,115,785	\$7 52
1907	1,158,590	7 42
1908	1,309,090	8 06
1909	1,400,000	9 09

In estimating the relative value of the per capita expenses it must be considered that the enrollment in public schools in 1909 was only 3 per cent of the population, whereas the normal proportion would be at least 12 per cent.

The Universities—The secondary schools prepare students for admission to the universities. The latter are four in number: San Marcos at Lima, having six faculties; San Antonio Abad at Cuzco, and San Augustin at Arequipa, four faculties each; San Tomas and Santa Rosa at Trujillo, the faculties of letters and law. The complete scheme of higher education is illustrated by the distribution of studies at the major university of San Marcos, Lima, which in 1910 was as follows:—

FACULTY	NUMBER OF STUDENTS
Philosophy and Letters	136
Mathematics and Natural Sciences	229
Political and Administrative Sciences	24
Theology	4
Law	140
Medicine	172
Total	705

The total registration in the four universities in 1910 was 1154 students.

For admission to the faculties of philosophy and letters, and of mathematical and natural sciences, a certificate showing that the candidate has completed the regular four years' course of secondary instruction is required; for admission to the faculties of jurisprudence and of political and administrative sciences, a certificate secured by two years' work in the faculty of letters; for admission to the faculty of medicine, the completion of two years' work in the faculty of sciences.

At the completion of five years' work in the faculty of medicine, of three years in the faculty of law, and of two years in the other faculties, the degree of A.B. is awarded. The completion of the full course, *i. e.* seven years in medicine, five in law and theology, and four in the remaining faculties, entitles the student to the degree of Doctor in the respective faculty.

Although the universities are under the general direction of the Minister of Public Instruction, they have a large measure of independence. The internal affairs of each are nominally regulated by the Rector and University Council, the latter consisting of representatives of the several faculties. In fact, these authorities have chiefly to do with

the fiscal affairs of the institutions, and the professors are practically independent in their work. The reorganization of the universities with a view to promoting internal unity and forceful administration is one of the most important problems before the education commission. On the scholastic side there is need of closer adjustment with the practical interests of the country. It is urged that a strong department of education should be created in the University of Lima, as a means of preparing students for the higher positions in the public school service. Already plans have been made for developing a commercial department in the University of Cuzco. This is due to the work of Dr. Alfred Giesecke, a graduate of the University of Pennsylvania, who was engaged to establish a commercial department in the college of Guadalupe, Lima, and who was subsequently appointed president of the university named.

The School of Agriculture and the School of Engineering together registered 200 students in 1910, which raises the total in higher institutions to 1354. The annual expenditure for higher education, universities, and technical schools, both included, is about, \$200,000. While Peru is looking to foreign countries, and in particular to the United States, for expert guidance in the effort to extend popular education and the higher order of technical training, there is an evident purpose to maintain the standards of professional training that are already well established. This purpose is indicated by the decree requiring foreigners who seek to practice either medicine or dentistry in that country to present the diplomas of their respective universities and also to submit to the same examinations as native applicants for professional sanctions. Even in the proposed reorganization of public instruction, care is taken to conserve the administrative system which experience has shown to be best adapted to present conditions.

PERUGIA, UNIVERSITY OF.—See ITALY, EDUCATION IN.

PERWICK, MRS.—The proprietress of an English girls' boarding school, one of the earliest of which we have any notice. This school, in 1643, was kept in the Black and White House, in Church Street, Hackney, London. The details about the school are given in a biography of Mrs. Perwick's daughter Susanne (1636-1661), written by John Bachiler. The girls (of whom Mrs. Perwick had about eight hundred) were taught principally by masters, thus continuing for schools the custom which had obtained in Tudor times, of employing a man as private tutor for the girls of the family, e.g. Roger Ascham for Princess Elizabeth, Richard Hyde for Sir Thomas More's daughters, and Christopher for Margaret Roper's daughters. Thus ten masters' names are given as teaching at Mrs. Perwick's school. Bachiler's book (published in 1643) advocates the "public" education of girls and argues that schools do not necessarily corrupt manners and morals. The subjects incidentally named as taught in the school are religious knowledge, reading, especially scripture, and music. In the latter the "grounds" were studied; and of instruments, the treble viol, the lyre, the harpsichord and the organ were all taught, and vocal music was cultivated. Dancing, including gesture and bearing, was an important object. The handwork taught and practiced included the needle, and work "by silver, silks, straws, glass, wax, gums, etc." Penmanship seems to have included accountancy. Housewifery and cooking were not neglected. On Sundays, the girls went to church close-covered with the hood. On return, they wrote out the sermon, made notes, and "reënforced daily prayers." F. W.

PESSIMISM.—In popular usage the disposition to look on the dark side of things; as a systematic philosophy, the theory that existence and life are radically evil, so evil that the only remedy is the negation of the "will to live," the exact antithesis of optimism (*q.v.*) as a philosophy. In considerable part, the motivation of pessimistic systems has resided in the superficial and complacent view of evil as an incident which contributes to the perfection of the whole taken by optimistic systems. Leibnitz's formula that this world is the best of all possible worlds obviously lends

itself readily to an extremely pessimistic interpretation. A certain pessimistic tone concerning the world as it *now* exists has also been a marked feature of the most serious and influential religions, such as Buddhism (*q.v.*) and Christianity. In general, nineteenth-century thought reacted in this as in other respects against the characteristic eighteenth-century thought, which had been optimistic. The latter held to the doctrine of natural harmony working inevitably for the increase of perfection and happiness; the former dwelt upon the existence of discord, struggle, and competition. The Darwinian idea of the omnipresence of the struggle for existence accentuated this tendency. While the pessimistic spirit found its most adequate expression in literature, especially poetry, it also found systematic metaphysical embodiment, notably in Schopenhauer and Von Hartmann. While systematic pessimism is too contrary to the needs of living beings to secure for itself many consistent adherents, it has made impossible the older type of optimism, and has been a leading factor in bringing about the transformation of optimism into meliorism. The latter holds to the reality of evil as a genuine fact, but emphasizes the possibility, through good will and intelligently directed effort, of a progressive amelioration. It is essentially a doctrine of progress. J. D.

See OPTIMISM; SCHOPENHAUER.

PESTALOZZI, JOHANN HEINRICH (1746-1827). — One of the world's greatest pioneer educationists, and a Swiss patriot who did much for his country by his work for social regeneration through educational reform.

Life and Career. — Born in Zurich, he lost his father when five years old, and was brought up almost wholly under the influence of his mother and a devoted servant. As a boy he was delicate, shy, awkward, dreamy, and unpractical. He passed through the elementary, preparatory, and Latin schools, and finished his education at the Public College of Zurich. In none of these did he distinguish himself as a student, owing to his want of accuracy and thoroughness in details, but he showed real ability and excelled in his grasp and understanding of principles. While still a youth he attached himself to the Swiss reform party — the country being at that time in the throes of social and political revolution — and was greatly influenced by two of his professors, Bodmer and Breitinger (prominent thinkers and literary men); the writings of Rousseau; and the friendship of Lavater, Füssli, and Bluntschli. He joined the Helvetic Society, took part in its debates and social activities, and wrote for its journal, *Der Erzieher*, articles criticizing the public corruptions of the time and urging social and educational reforms. Touched by the poverty and ignorance of the poor, which he saw in the parish

of his grandfather, Pastor Hongg, he resolved to prepare himself for pastoral work, but changed his mind after his first attempt to conduct a service. Then he began to study law, with a view to help his country through local and national affairs. Overwork in this, and shock at the sudden death of his friend Bluntschli, brought on a serious illness. His doctor advised him to give up study and live an open-air life. The writings of Rousseau and the Physiocrats had already led him, with other enthusiastic students, to make amateur experiments in the return to the life of nature; and he was quite willing to take to the simple life. So he burnt all his books, vowing never to read one again, and turned farmer in 1767. Two years later he bought a farm in the canton of Aargau, and took to himself a wife. His young and beautiful bride, Anna Schulthess, proved a gifted and devoted wife, a helpmeet for him through all his sufferings, failures, and successes.

Neuhof — As a farmer his brilliant but erratic gifts were his downfall. After seven years of struggle he found himself in desperate straits as a man of affairs. But as a man of ideas he had begun to find himself in these same seven years of failure. At Neuhof, as he called his farm, was born to him a son whose early education he himself undertook, and thereby began his educational discoveries. His observations, experiments, and experiences in the education of his little boy "Jacobli," proved a pioneer effort in practical child study, or experimental pedagogy, and was the beginning of his formulation of the practical principles of education according to nature. Basing his attempts on the theories of Rousseau, he was led to modify and correct many of this great writer's views. From the beginning of 1774, when his son was three and a half years old, he kept a regular record of his work with him in *A Father's Journal*, and therein are to be found all the great root principles of his final views on education; in particular, the principles of intuition and sense perception as the only real bases of true education. He had also begun to develop ideas on the education of the children of the poor from the industrial standpoint. The barrenness of the farm and his unsuccessful management led him to set up cotton spinning as a means of livelihood in 1774. To do the light work connected with this, he employed the children of the very poor, so that they might be rescued from mendicancy, enabled to earn their bread, and pay something towards their education. Workhouse children were sent to farmers in those days, and were often turned out to beg their bread. Pestalozzi's central idea was that the employer should be responsible for the education of young employees. But in cotton spinning also he failed, from the practical point of view, and was soon absolutely at the end of his financial resources.

But just at this time he had the good fortune to be introduced to Iselin (*q.v.*) at a meeting of the Helvetic Society. Pestalozzi discussed his view on industrial education with Iselin, who encouraged him, and advised a public appeal for support. This was drawn up in December, 1775, and published in Iselin's journal (*Die Ephemeriden der Menschheit*) in 1776, as an appeal to "The Friends of Humanity" to support the Neuhoof industrial school. The appeal was successful, and Pestalozzi was able to add to the twenty children already in his employ. He undertook to teach them to read, write, and calculate. The boys were to be taught all the practical processes of small farming, so far as this could be done at Neuhoof; the girls, gardening, domestic work, and needlework, and all were to do cotton spinning. All were to receive such a religious education as would develop in them pure and tender hearts. The subscribers were to receive reports on the work of the institution. The appeal, two reports, and three letters, which all appeared in *Die Ephemeriden*, and another report on the school published as a pamphlet, set forth Pestalozzi's views on *The Education of Poor Country Children* (1777-1778). There were seventeen boys and twenty girls in the school in 1778. Two years later the whole thing collapsed because of financial difficulties due to Pestalozzi's business incapacity. He and his family were ruined, and became poorer than some of those whose sufferings they had learned to understand, and for whom they had sacrificed themselves.

Literary Activity.—In this dire distress his pen was his only means of support. Encouraged by Iselin and Fussli, he began to write: first a series of short maxims on education, morals, and religion, for Iselin's journal, under the title *A Hermit's Evening Hours*; then a prize essay (dividing first prize with another writer) on *Sumptuary Laws*; and soon after a skit on the clothing of a town watchman, during 1780. The last of these was seen by Fussli's brother (the painter), and caused him to suggest that Pestalozzi should write a story. The result was *Leonard and Gertrude* (1781), a romance of rural life, based on his own experience and knowledge of the lives of the poor, and expressing his views on social reform and regeneration through home and school education and democratic local government. It revealed Pestalozzi as a writer of original and exalted powers, met with great and immediate success, and has become a world's classic. He calls it "a book for the people," and wrote four other parts of it in 1783, 1785, 1787, and 1826, respectively. Feeling that the main purpose of the book had been missed by its readers, he published another to point its morals. This was *Christopher and Eliza* (1782), "my second book for the people," in which a peasant family read and discuss *Leonard and Gertrude*. It

was not a success. During 1782 he conducted a weekly paper, *The Swiss Journal*, in which he wrote on education, politics, and morals. It only lasted a year. In 1797 he made a third attempt to explain, by parables or fables, his *Leonard and Gertrude* in a book entitled *Figures for my ABC Book*. From 1783 to 1797 he published several political essays. At the suggestion of Fichte (*q.v.*) he endeavored to work out the philosophical bases of his views on education, and after three years of laborious study published his *Investigations into the Course of Nature in the Development of the Human Race* (1797).

Stanz.—On the 9th of September, 1798, occurred the battle and massacre at Stanz, one result of which was that a poorhouse had to be provided to shelter the homeless orphans of the neighborhood. Pestalozzi was asked to take charge of this, and eagerly consented. No conditions could have been more unfavorable for testing his theories,—half-restored ruins for a school building, himself the only teacher; a peasant and her young daughter the only domestic servants for a household of eighty; distrusted as a heretic by the inhabitants; without sufficient furniture or school apparatus; and with many of his pupils very dirty, degraded, and diseased, he was overwhelmed with worry and work. But he was filled with a great hope and a great zeal; he would realize the picture of Gertrude's school at Bonnal. Physical education in the form of play, drill, and industrial work alternated with mental and moral culture through reading, writing, arithmetic, and living the good life. Simultaneous repetition was much used in lessons, and older and more advanced children put to teach others. No books were used, nor was there any definite syllabus or time-table. Yet, in spite of all defects, there were splendid successes, and all who saw the work were amazed and delighted. But the school which received its first pupils on the 4th of January, 1799, was closed at the beginning of June, in the same year, so that the building might be used as a military hospital. Pestalozzi retired to the mountains to recruit his seriously impaired health. After a few weeks' rest—which probably saved his life—he returned to Stanz, anxious to resume his work; but meantime other arrangements had been made.

Burgdorf.—Through the influence of Minister Stapfer (Arts and Sciences) he obtained a post in a school in Burgdorf, under a headmaster who was a working shoemaker. He was given a small salary, and lodging in the castle, on condition that "his work benefited the pupils and furthered the perfecting of his method." Some parents, urged on by the schoolmaster, raised an outcry against experiments being made on their children, and Pestalozzi was transferred to an infants' school, with twenty-five pupils from five to eight years old (boys and girls) under a mistress.

Here he had full liberty and directed his experiments to the discovery of the psychological laws and the simplest methods of teaching. He began the plan of teaching through language, number, and form, and was remarkably successful, though he still used simultaneous repetition and had no time-table. And now fortune was kind to him:—he met Fischer, the head of the training college for teachers in the castle of Burgdorf, who was formerly professor of philosophy and pedagogy at the Bern University, and a disciple of Salzmann (*q.v.*) the Philanthropist. They became friends, and Fischer, later on, introduced Krüsi (*q.v.*) to him. When Fischer died rather suddenly in May, 1800, the castle was handed over to Pestalozzi and Krüsi, who proposed to carry on a training college, a secondary boarding school, an elementary day school, and an orphan asylum; and to combine with their work experiments in education and the publishing of books thereon. In a short time the staff was increased by the arrival of Buss, Tobler, and Niederer (*q.v.*), who became and remained loyal, devoted, and self-sacrificing colleagues, and together with Krüsi introduced method, order, and thoroughness into Pestalozzi's plans. Under them Burgdorf was the center of educational experiments, investigations, and training such as the world had not hitherto seen. High and low came from all parts to admire and to learn. Here Pestalozzi published (1801) *How Gertrude teaches her Children*, in which he expounded his principles and methods of education, so that—as he thought—the psychology and practice were reduced to such simple terms that every mother could understand and use them. All who wish to understand education according to Pestalozzi must read this book. It makes and marks an epoch in education and is the source of many of the best and most modern views. For the guidance of parents and teachers, Pestalozzi and his staff published the following elementary books during 1803: *The Mother's Book*; *The ABC of Intuition, or the Intuitive Teaching of Form Relations* (in two parts); and *The Intuitive Teaching of Number Relations*. These books explain his underlying ideas in teaching speech, form, and number, and give detailed examples of lessons in these subjects. They are intended to be used only for young beginners. By such means Pestalozzi worked out his ideas and spread them abroad. He achieved fame and success, and did his very best work, at Burgdorf.

Yverdun.—In July, 1804, Pestalozzi had to vacate the castle, which was required for governmental offices. An arrangement was made for the institution to be housed at Münchenbuchsee, near to Fellenberg's Institution at Hofwyl; and the practical direction of it was committed to Fellenberg (*q.v.*), while Pestalozzi continued to be the proprietor.

Unhappy differences arose between them, and, in July, 1805, the agreement was canceled and Pestalozzi's Institution was removed to the castle at Yverdun, where it continued till its end on March 2d, 1825. The first five years of this time were years of brilliant successes in which the institution became world famous. After this came private and public misunderstandings, strife, humiliation, and decay; and the less said of these the better. But the worse matters became the more Pestalozzi returned to his original and constant idea of the education of the poor. He started the Clindy Poor School (1818); and at the moment of final failure his one great wish (unfulfilled) was to transport it to Neuhof. At Yverdun the method was applied to older pupils from many countries; to more advanced stages of school subjects, including classics; and to the education of girls in a separate school. Pestalozzi's chief writings from 1805 to 1827 were: the *Weekly for Human Education* (1807–1821), in which appeared his *Lenzburg Address*; the *Discourse on the Idea of Elementary Education* (1809), a *Report on the Condition and Organization of the Yverdun establishment* (1808); Nageli's articles on the teaching of singing, etc.; *Views and Experiences relating to the Idea of Elementary Education* (1807); *Addresses to the whole school* (1808–1813); the *Swansong* (1813), the first part of which is *On Education according to Nature*; and *Letters on Early Education* (1818), written to an Englishman. His political enthusiasm had endured and he wrote important political pamphlets. The closing year of his life found him faithful to his three great purposes: as friend of the poor he was engaged in reestablishing his industrial school at Neuhof; as political reformer he wrote an address *On Fatherland and Education*, for the Schinznach Helvetic Society, of which he had been elected president; and as educationist he wrote a paper entitled *An Attempt at a Sketch of the Essence of the Idea of Elementary Education*, for a meeting of the Brugg Society for the Promotion of Education, at which he was present.

Educational Theories—Though Pestalozzi never wrote a clear, systematic, and complete account of his theories, his writings and work give the material for a definite outline of his views. Fischer, Chavannes, Jullien, Niederer, Morf, Mayo, Krüsi (junior), and Payne have all given such outlines. The foundation of his doctrine is that all human development and power spring from possibilities native to the human being, i.e. "the growth of man is God's work, and the result of universal laws conferred on his nature"; that "the moral, spiritual, and artistic capabilities of our nature must grow out of themselves"; that "a man's powers are all part of an organic whole"; that "nature develops all the human faculties by practice, and their growth depends

upon exercise"; and that man's development is itself organic, i.e. "the individual and separate organs of his being form themselves gradually into unison." Hence, the function of the educator is to assist "nature's march of development" so as to secure a natural, symmetrical, and harmonious progress; thus "improving the tendencies and powers of humanity." These fundamental truths lead to the following general principles: (1) *Education must be essentially religious*, since man has a divine origin and end. (2) *Education must develop man as a whole*. It must draw out all his moral, mental, and physical powers, in a balanced and harmonious progress at every stage; "the development of human nature, the harmonious cultivation of its powers and talents, and the promotion of manliness of life: this is the aim of instruction." We must develop the powers of "the head, the hand, and the heart," concurrently and according to the nature of each. (3) *Education must guide and stimulate self-activity*. "The only means of development our powers possess is their use." The educator must do as little as possible; his work consists "in a continual benevolent superintendence—giving a helping hand to the instinctive efforts after self-development." (4) *All education must be based upon intuition and exercise*. This is Pestalozzi's great theory of *Anschauung* (g.v.), by which he means "the immediate and direct impression produced by the world on our inner and outer senses, i.e. the impressions of the moral world on our moral sense and the physical universe on our bodily senses." Sense experiences need to be elaborated and organized through observation, and the learner must, therefore, acquire a true art of observation, i.e. the thorough and exact grouping, separating, and combining of objects. (5) *Education must observe a right graduation and progression in development*, for "there is in nature an order and march of development, and if you disturb or interfere with it you make the powers of the mind weak, unstable, and unbalanced." "Each child should be taught that which he has to learn at the time his nature calls for it, for this is proof that his sensibility and power are ready for it." The child repeats the history of race in its development. Each stage of development must grow out of the preceding and into the following stage by scarcely perceptible additions. Mind and body are one, and, therefore, practical power must develop with knowledge, and practical skill with insight. Both must proceed from the known to the unknown; the simple to the complex; and the near to the remote; and always in relation to the experiences of real life. (6) *Education must foster the growth of knowledge through the development of ideas*. From mere vague impressions the mind must evolve values and meanings. From "a swimming sea of confused sense-

impressions" some one thing stands out as a separate something, i.e. the person has a *distinct* idea of it. Next it may be observed more fully and in detail, so that the person can describe it accurately, i.e., he has a *clear* idea of it. By further analysis and by combining and comparing it with other objects, he is able to define it, or state its essential qualities so as to mark it off from all other objects; i.e. he has a *definite* idea of it. This progress of ideas is obtained through getting to know how many, and how many kinds, of objects appear in consciousness; investigating what their form and outlines are; and abstractly thinking about these by the help of words, i.e. through number, form, and language.

From the foregoing six principles follow certain practical rules for the educative process. (1) *An all-round training must be given*. (2) *All possible liberty must be allowed to the learner*. "The nature of the child must determine all the details of his education." Enlightened affection and confidence, and geniality, must exist between teacher and pupils. (3) *Work is more important than words*. "Work in general is the surest of all exercises for the attention," and "man is much more truly educated through that which he does than through that which he learns." Knowledge without practical power, or insight without the ability to apply it, is a "fearful lot for a human being." Words may "not only destroy the powers of attention to the impressions of nature, but mar the very susceptibility toward them." Our activities are "the sense-foundation of our virtues." (4) *The method of learning must primarily be analytic*, i.e. based upon the analysis of experience. "We put our children on the road which the discoverer of the subject himself took, and had to take." A pupil at Yverdon writes "we are made to invent geometry, the masters contenting themselves with pointing out the end to attain; and putting us on the road to it." (5) *Realities must come before symbolism in learning*. "Elementary education must aim at establishing connections between the child and the realities of his actual life." Sense-perception is the one sure basis of thought and judgment which are developed through language, and therefore this order must be observed, whilst maintaining harmony between experience, thought, and language. Hence, the great importance of object lessons and science. We "get knowledge by our own investigation, not by endless talk about the results of art and science." "I desire to make the effect of words and talk on the mind of little account, and to secure that dominating influence proper to the actual impressions of physical objects." (6) *Organization and correlation are necessary*. This applies to the relations between mind and body, the nature of the child and of knowledge, and the pupil and school conditions. H. H.

Pestalozzi's Influence.—The influence of Pestalozzi very soon spread over Europe and into this country. His influence was most profound in Germany, where Pestalozzian methods were employed as the means for the regeneration of the country after the disaster at Jena. Young Germans were sent to Switzerland to study by the side of the master and returned to their country full of enthusiasm for the new movement. Among these the following may be mentioned, while for further details the reader is referred to the separate articles: Fichte, Froebel, Herbart, Rütter, Harnisch, Zeller, Ramsauer, Plamann, Dinter, Diesterweg, and many others, who contributed by a reconstruction of theory or practice to the reform of methods of instruction in elementary schools and in the training of teachers. In another direction Pestalozzian influence was also powerful; namely, the reform of philanthropic educational institutions and orphan asylums. In Switzerland Pestalozzian methods were early adopted, and through his immediate assistants Pestalozzian influence soon made itself felt. Among these may be mentioned Hermann Krüsi, Sr. (*q.v.*), Gustav Tobler, Nageli (*q.v.*), and De Guimps, while the work of Fellenberg, Wehrli, and Père Girard (*q.v.*) was also inspired to some extent by Pestalozzi.

At the time when she might have profited greatly by the Pestalozzian movement, England was too deeply interested in the monitorial system of the two educational societies. But she was not entirely unaffected by the movements, for through James Pierpont Greaves (*q.v.*) and the Infant School Society (see INFANT SCHOOLS), and through the Mayos, Charles and Elizabeth (*q.v.*), and the Home and Colonial School Society (*q.v.*), some little influence was exerted on English education, even though in the latter case it was somewhat perverted.

In no other country, perhaps, was the Pestalozzian movement so widespread as in the United States. Introduced and naturalized by William Maclure (*q.v.*), the practical side was well illustrated by Joseph Nefé (*q.v.*), whom Maclure induced to come to this country. The work was a few years later taken up in New England, and its chief representatives were William Russell, J. G. Carter, Charles Brooks, William C. Woodbridge, A. Bronson Alcott, Lowell Mason, and Henry Barnard (*q.v.*). This influence was expressed not only in the introduction of reformed methods in schools, but in the foundation of normal schools and a greater interest in public education. The strongest influence, perhaps, radiated from Oswego (see OSWEGO MOVEMENT), whither by different routes the Pestalozzian influence found its way and where too it led to improved schools and the training of teachers. Trained by Edward A. Sheldon and his daughter Mary Sheldon Barnes and by Hermann Krüsi, Jr.

(*q.v.*), teachers in turn spread the Pestalozzian movement far and wide in this country. The culminating point of the movement may be said to have been reached in the introduction of Pestalozzian methods in the schools of St. Louis by W. T. Harris (*q.v.*). Elsewhere the influence of Pestalozzi, if it went no further, may be recognized in the introduction of object teaching (*q.v.*) into the schools. H. H.

PESTALOZZI-FROEBELHAUS.—An institution established in Berlin for the propagation of Pestalozzian and Froebelian methods and the training of kindergarten teachers. The departments of this school are: (1) a public kindergarten for children from 2½ to 6; (2) an intermediate class for children from 6 to 6½; (3) an elementary class for children from 6 to 7½; (4) manual trade school for boys and girls up to 14; (5) a cookery school; and (6) training school for kindergarten teachers. (For photograph of the school, see article on KINDERGARTEN.)

PESTALOZZI VEREIN.—The name borne by a large number of elementary teachers' benevolent associations in Germany for the support primarily of orphans and widows of

teachers. To celebrate the centenary of Pestalozzi's birth, a movement was begun under Diesterweg's (*q v*) influence to found a number of orphanages. It was soon felt, however, that it would be preferable to establish a fund to board out orphans and not deprive them of family life. The Pedagogical Association of Dresden established the precedent. In 1846 a number of other organizations bearing the title of *Pestalozzi-Verein* sprang up, and in fifty years spread throughout the whole of Germany. The purposes of the funds were soon gradually extended,—a change made possible by the improved conditions of the teachers in the shape of higher salaries, pensions, and provision for widows and orphans. The funds are now used for the support of (1) orphans up to the age of fourteen or fifteen; (2) of orphans beyond those ages; (3) of widows; (4) of the blind; (5) of needy and convalescent teachers. The funds are obtained from voluntary contributions, concerts, and sales of books, songs, magazines, calendars, etc. A number of societies, however, have practically become insurance companies by making support and its amounts depend on fixed contributions. In this way they have placed themselves under the Imperial Law for Private Insurance Enterprises of 1901.

PESTILENCE. — See **EPIDEMICS**.

PETER THE LOMBARD (1100–c. 1160).

—Theological teacher born at Novara in Lombardy. He studied at Bologna, Rheims, and Paris. At Paris he was, probably, a pupil of Abélard. It is certain, in any case, that he was a careful and sympathetic student of Abélard's method. After being advanced to several ecclesiastical dignities, he was made Bishop of Paris about the year 1158. He soon resigned his see, and died at some time between that year and 1160. Peter owes his importance in the history of education to his *Books of Sentences* (*Quattuor Libri Sententiarum*) written about the year 1145, or, perhaps, a few years later. Although the book and the method which it embodied met with violent opposition at first, especially from the mystics of the School of St. Victor, both ultimately prevailed. The *Sentences* became the textbook of theology in the Schools; it was commented on by all the great teachers in the thirteenth century; its arrangement of topics was followed and its method adopted in all the subsequent *Summae*, or textbooks of theology. In substance it is orthodox, although a few propositions taken from it were formally condemned. It was recognized by the academic authorities in Paris and Oxford in the thirteenth century as the official textbook,

the candidate for the degree of *Magister* being obliged to lecture on the *Sentences* for two years. The essence of its method is dialectical. It is, however, positive, also. Its quotations from the Fathers and the Scriptures are abundant, and one of its chief merits is that it makes use of the *Decretum* of Gratian of Bologna (about 1140). W. T.

PETRARCH, FRANCESCO (1304–1374).

—The great Italian poet and humanist, born at Arezzo, whither his father had fled from Florence. After several changes the family removed to Avignon in 1313, where Francesco studied the humanities for four years under the direction of Conventino of Prato. But his studies did not accord with the wishes of his father, and in 1319 he was sent to Montpellier to prepare for the legal profession. On the death of his father, in 1327, however, he returned to Avignon and shortly after took priestly orders. It was about this time that he met Laura, who inspired his *Canzoniere* and *Sonnets*, which brought him into marked prominence and won for him the favorable notice of men of influence. In 1333 Petrarch yielded to a restless desire to see the world and visited Paris, Ghent, Boulogne, and Liège, meeting well-known scholars and adding to his collection of classical Mss. In 1337 he withdrew to a quiet retreat at Vaucluse, near Avignon, and there published the Latin epic on *Africa*, on the appearance of which he was hailed as the poet laureate of Italy. In 1341 he received the laurel crown from the hands of a Roman senator upon the hill of the Capitol.

During this period three events took place of some importance in shaping Petrarch's life and thought. In 1345 Cicero's *Familiar Letters* were discovered, and Petrarch became the eager student of that famous Roman whom he always acknowledged as his master. In 1348 Laura died, and there can be no doubt that her death was a profound loss to the poet she had so long inspired. But two years later, while passing through Florence on his way to the jubilee at Rome, Petrarch met Boccaccio and then began what was destined to be the deepest and most satisfying friendship of his life. It was beyond question Petrarch's eager

enthusiasm for the new learning which inspired his friend and made of Boccaccio another powerful instrument in the spread of humanism.

In 1353 Petrarch abandoned Vauluse and took up his home in Milan at the court of the tyrant, Giovanni Visconti. Here he held the position of court orator and ambassador, and was sent upon many brilliant missions, notably to Charles IV in 1356. His final home was made at or near Padua under the patronage of the despot Francesco di Ferrara. Here, in his later years, he met the Byzantine Greek teacher Leontius Pilatus, and apparently made an earnest attempt to learn the Greek language. But it is clear that he never mastered its difficulties, for in his well-known letter to Homer (*Fam.* XXIV, 12) he acknowledges that he was "not so fortunate as to have learned Greek." In 1369 Petrarch sought the quiet of the little village of Arquà in the Euganean hills, where he studied with the most unremitting industry, employing a large number of secretaries and copyists. Here he was found dead among his manuscripts and books on July 18, 1374.

The personality of Petrarch is hardly less interesting to the student than his work. In him first flamed the ideal of self-culture, interpreted as the development of a free, enlightened personality through the medium of classic prose and verse. Religious as he was, the conflict between his spiritual interests, as he conceived them, and his intellectual desires was a very real one. Introspective interest in his own mental states, his own soul struggles, mark Petrarch as the first modern man in this regard. The reader has only to scan the pages of his *Confessions* (*De Contemptu Mundi seu suum Secretum*) to appreciate how conscious of self, of the interest and worth of personal aspiration and struggle, is this pioneer of a new intellectual world-order. While he heaped contempt upon the Averroists for a materialism closely bordering upon atheistic impiety, he yet found it difficult not to regard the great classics of Rome with the same veneration that he bestowed upon the Scriptures. To his impassioned mind Homer, Cicero, and others of the ancient writers lived again, and in his *Letters* he addressed them with enthusiastic greeting. Animated by his ideal of self-culture, he refused appointments which few men would have felt justified in rejecting. Yet in the very heart of his ideal were elements of weakness which increasingly characterized the intellectual revival for which he labored—the tendency to define self-culture as æsthetic and literary appreciation rather than in terms of a dominating social and moral conviction.

When we turn to the scholarship and achievements of Petrarch we cannot fail to recognize the unique character of his services to human culture. He was indefatigable in

his zeal for the collection and accurate transcription of manuscripts. Possessed of a truly remarkable power of arousing enthusiasm in others, he influenced a wide and varied group of acquaintances, through his vivid personality and his no less vivid correspondence, and enlisted them in the cause of the new enlightenment. He was in truth the mouthpiece of his age, voicing with enthusiastic conviction what other men felt more vaguely. His scholarship was genuine, if not profound, and was the product of years of intense industry and careful analytic thought. His zeal for the exact transcription of the precious Mss., thus far collected from musty corners of schools and monasteries, led him bitterly to deplore the careless methods of the copyists of his day.

Petrarch's writings comprise his Italian verse (*Canzone* and *Sonnets*), his Latin *Eclogues* and *Epistles*, with the epic of *Africa*, his *Historical Anecdotes*, *Lives of Famous Men*, *Life of Julius Caesar*, and certain miscellaneous writings, including the *Confessions*, *Orations*, and minor *Essays*. There should be added two serious works on *The Life of Solitude* and *On Monastic Leisure*. His library, dedicated to the Republic of Venice, probably never reached that city. After passing through the hands of the tyrants of Padua and Pavia, twenty-six volumes found their way to the National Library in Paris, where they now remain. A few of his other manuscripts are divided among the cities of Rome, Florence, Padua, Milan, and Venice; but a large number have never been accounted for.

PETTY SCHOOL.—Schools or classes preparatory to grammar schools in England. The grammar school did not admit pupils until they had learned their "accidents." The petty school received pupils from the age of five and kept them until they could be admitted to the grammar schools, or about three years. The curriculum consisted mainly of learning the A B C and reading of English, with elements of Latin grammar. The term "petty school"

did not come into use until the seventeenth century, but the terms "petties," "petits," "pettetes," primarily young children, are already found in the preceding century for lower school pupils. The master of the grammar school was not expected or compelled to teach the petties; they might be under the charge of an usher, or the master might "assign so many of his scholars in the third and fourth forms as may suffice to instruct them" (Guisbrough Grammar School, 1561). Of course the preparatory training of the petties might be given by private schoolmasters, dame schools (*q.v.*), song schools (*q.v.*), etc. As used by Hoole (*q.v.*) in his pamphlet on the *Petty School*, the use of the term is extended to include not only pupils preparing for the grammar school, but those who are unable to profit by a grammar school education and remain in the petty or elementary school for a curriculum including English literature, writing, and arithmetic. This use may be compared with the *Petites Ecoles* (Little Schools) of the Gentlemen of Port Royal (*q.v.*), a use of the term which was common in Paris in the Middle Ages for elementary schools, as opposed to the high or grammar school (*Grande Ecole*) under the chancellor.

See ABCDARIANS.

PETTY, SIR WILLIAM (1623-1687) — Political economist, born at Romsey, England, the son of a clothier. After attending the grammar school at Romsey and early showing considerable mechanical ability, he went to sea, and later entered the Jesuit College at Caen in France. For a brief period he was in the royal navy, but later he studied at Utrecht, Amsterdam, and Leyden, whence he proceeded to Paris, where he met Hobbes and Father Mersenne, mathematicians and friends of Descartes. On his return to England he took up his father's business for a time and invented a manifolding machine, the "Pentograph," which brought him considerable fame. He again took up the study of medicine, which he had begun at Leyden, and took the degree of Doctor of Physic at Oxford in 1649 and became fellow of Brasenose College and professor of anatomy in 1651. He was appointed physician-general to the army in Ireland in 1652, and while there helped to survey the country in a scientific manner and with much rapidity and thoroughness. At the Restoration, Petty, who sympathized with the Cromwellian party, was deprived of his appointment, settled in London, and became a member of a scientific coterie there. On the incorporation of the Royal Society (1662), which in part was inspired by an early work of his, Petty was knighted. He devoted much time to mechanical inventions, among them "a wheel to ride upon" and a double-keeled vessel. Both Evelyn and Pepys speak in high praise of his versatility.

Of his writings the larger number deal with

questions of political economy. He urged the establishment of a statistical bureau, and himself wrote a number of essays in *Political Arithmetick*. In 1662 he wrote a *Treatise of Taxes and Contributions*, which gives a correct account of the origin of wealth. In the field of education, his most interesting work is the *Advice of W. P. to Mr. Samuel Hartlib, for the Advancement of some particular Parts of Learning*, written in 1647-1648. It consists of four parts. The first commends Hartlib's proposed *Office of Publicke Addresses*, a central bureau of information, research, and compilation of bibliographies. Various departments are described and in their comprehensiveness recall Bacon's *New Atlantis*. The "Gymnasium Mechanicum or Colledge of Tradesmen for the Advancement of all Mechanical Arts and Manufactures" was to be an institution for the encouragement of workmen to perfect their work; they were to be granted free dwellings and fellowships to encourage them in continuing at their particular branch. The study of pure science was to be pursued at the "Nosocomium Academicum," a combination of hospital, museums of different kinds, observatory, library, collections, "an Abstract of the whole world."

The education of children is dealt with in the second part of the *Advice*.

Petty in his comprehensive view of the school does not neglect the teachers, and hopes that "the business of education should not be (as now) committed to the worst and unworthiest of men, but . . . be seriously studied and practised by the best and ablest persons." To this end he recognizes the value of a study of individual children and advises "That effectual Courses be taken to try the Abilities of the Bodies and Minds of Children, the strength of their Memory, inclination of their Affections either to Vice or Virtue, and to which of them in particular, and withall to alter what is bad in them, and increase and improve what is good, applying all, whether good or bad, to the least Inconvenience and most Advantage."

Petty's *Advice* should be classed with Milton's *Tractate* and Locke's *Thoughts* among the most valuable contributions to the development of educational theory in England.

PHARMACY, EDUCATION IN. — **Historic Development.** — In order to understand the present status of pharmaceutical education in this country, it is necessary to recall that, unlike the learned professions, pharmacy is still clinging to the apprenticeship system, and this in spite of the universally recognized

deterioration of the modern drug store as an educational factor.

Though the pharmacist has had his precursors in antiquity and during the middle ages, he traces his direct descent from the Italian apothecary of the Renaissance, who had his professional birth in the edict of 1224, issued by the emperor Frederick II. This edict created the public apothecary and established his relation to the physician and to the public. From Italy the apothecary crossed the Alps into Germany, France, and England. Although some of the apothecaries completed their education at the Italian and later at other universities, the large number were trained exclusively in the shops of their preceptors. In England they seem to have played, at least in part, the rôle of assistants to physicians, as seen in Chaucer's *Canterbury Tales*; later they entered into serious competition with the physicians, and since the beginning of the eighteenth century have been licensed as general medical practitioners. Their place as apothecaries, in the continental meaning of the term, was filled by the present-day chemist and druggist.

In Paris the apothecaries were organized into a gild, first with the wealthy spicers, later independently of them. As such they had charge of the education and examination of apprentices. Shortly before the French Revolution the apothecaries' gild of Paris was reorganized as a college of pharmacy, *i. e.* as a corporation of the master pharmacists. Being thus proclaimed as professional rather than as commercial men, the duty of the proper education of their apprentices was thereby made more important than before. However, the Revolution disposed of all special privileges. Since then the education of the prospective pharmacist has been regulated by the state.

In Germany, where the system of concessions of apothecary shops was continued after the political and economic reorganization that followed the Napoleonic wars, the apprenticeship was taken very seriously. The apothecary shop served not only as a means of educating the pharmaceutical apprentice, but, before the days of Liebig's laboratory at Giessen, also as almost the only means of acquiring a practical knowledge of chemistry. Hence Liebig, although he wanted to become a chemist, served an apprenticeship in the apothecary shop at Heppenheim. Indeed, it would seem that Trommsdorff's private school, maintained in connection with his apothecary shop at Erfurt, must have suggested the idea of laboratory instruction to Liebig.

In England the development of pharmacy was hampered not only by commercial, but by medical tendencies. Among the small traders on Chepe Street, London, were the spicers and pepperers, the latter being organized into

a gild as early as 1180. Out of these developed the grocers, the sellers *en gros*, who received their first charter in 1429. On them were conferred the charge of the king's bean, the exclusive power of garbling drugs, spices, and imported merchandise, and the duty of examining the drugs and medicinal wares sold by the apothecaries.

The earliest apothecaries in England appear to have come from France in the fourteenth century. Not satisfied with the mere preparation of medicaments, they soon indulged in medical practice. Their charter of 1617 freed them from their old enemies, the grocers, but their medical practice brought them into conflict with the College of Physicians incorporated in 1511. After a long quarrel, in which even men of letters took part, the apothecaries came out victorious in 1703, since which time they have been recognized in England as medical practitioners. Preferring the keeping of shop to medical practice, some of the assistants of apothecaries, as well as others, developed into druggists proper, such as was Druggier, one of the characters of Jonson's *Alchemist*. Conflict between these and the apothecaries over the recommendation of medicines for the sake of gain, led to the incorporation of the Pharmaceutical Society of Great Britain in 1842, which was given power to control its own educational policy.

Such a development, coupled with the general *laissez faire* policy of England, could not produce a highly developed calling of the pharmacist. The chemist in England, as Liebig wrote to his friend Woehler in the fifties of the past century, is not a chemist but an apothecary. Yet according to English laws, the apothecary is a general medical practitioner, not an apothecary or pharmacist in the continental sense of the word.

United States.—Although the colonies and the original thirteen United States obtained such meager pharmaceutical literature as was available to them almost entirely from Great Britain, the idea of organizing local colleges appears to have been taken from France. Thus, when the University of Pennsylvania in 1821 took steps to improve the educational status of the local apothecaries, some of the Philadelphia druggists resented this as interference, and organized a college of pharmacy, *i. e.* a corporation of local druggists. One of the objects of this body was to provide more systematic instruction than could be offered to apprentices in the exacting occupation of drug-store life. Evening lectures during the winter were provided and a "school" was started by the college.

The other larger cities followed the example of Philadelphia in the organization of some of the more ambitious local druggists as colleges of pharmacy, viz. Boston in 1823, New York in 1829, New Orleans in 1838, Baltimore in 1841, Cincinnati in 1850, Chicago in 1859,

St. Louis in 1864, Mobile in 1866. But whereas the Philadelphia College of Pharmacy began its educational activities almost immediately, the Massachusetts College of Pharmacy, although the second to effect organization, did not seriously assume its educational obligations until 1868.

As already pointed out, these colleges of pharmacy were corporations of local druggists organized for general professional purposes. Incidentally most of them provided more or less regular courses of evening lectures for the benefit of their apprentices, and later for such others from a distance as did not enjoy similar advantages at home. An attempt to foster pharmaceutical education by means of a conference of delegates of the colleges—not of the faculties of their schools, it should be noted—was made between the years of 1870 and 1882, but failed. During this period six new colleges were organized, viz. those of Louisville (1870), San Francisco (1872), Washington (1872), Pittsburg (1873), Albany (1881), Cleveland (1882).

It was about this time that the state universities of the old Northwest Territory began their period of phenomenal development. The University of Michigan, which had given pharmaceutical instruction since 1868, reorganized this department in 1876. Wisconsin followed in 1883, Indiana in 1884, Ohio in 1885, Illinois in 1887 (since abandoned for an affiliation with the Chicago College of Pharmacy). Since then many states west of the Mississippi have offered similar courses of instruction. Owing to the lack of endowment or other support, the older colleges had to restrict their required instruction to lectures and occasional quizzes. With the state universities, the laboratory at once took its place as one of the most important means of imparting instruction in the basal sciences and their pharmaceutical application.

The fourth period is that of the second conference, the Conference of Pharmaceutical Faculties, organized in 1900. Of possibly more than eighty institutions in the United States, thirty-two belonged to this conference in 1910. Its standards are still very low, but it must be remembered that, until favored by legislation, the older eastern colleges had no entrance requirements whatever. Although a prerequisite law has been in force in the state of New York since 1905, the minimum number of hours of instruction demanded by the Department of Education does not yet exceed 1200 hours, about one half of which must be laboratory work. The state universities demand about twice this amount in their two-year courses. Based on one year of high-school work as a general preparation, and in many states not even that, pharmaceutical education in this country has still much to strive for.

In order to appreciate why such a low standard prevails in spite of the desire of many

an institution to raise the standard, it is necessary to know that the state boards of pharmacy, and not the educational institutions, are the controlling factor. Since about 1875 the practice of pharmacy has been controlled in one state after another by legislation. These state pharmacy laws have created state boards which pass upon the qualification of candidates for registration. As a rule, two classes of pharmaceutical practitioners are recognized by these laws: first, the registered pharmacist, who enjoys full privileges in the practice of his calling; and second, the assistant pharmacist, who enjoys limited privileges only. Until recently no special schooling of any kind was demanded. In addition to the requisite four or five years of drug-store experience demanded by law, the prospective pharmacist could prepare himself for the state board examinations in whatever manner he saw fit. Quiz compends and cramming schools have played an important rôle in this preparation for the state boards. Correspondence courses have also given some aid. Inasmuch as in the case of failure a candidate can repeat *ad libitum* his experience before the board, these examinations themselves have been a farce.

New York was the first state to have a pharmacy law. About thirty-five years later it became the first state to enact prerequisite legislation, i.e. legislation making graduation from a recognized school a prerequisite to the state board examination. Similar legislation will no doubt spread. Thus a minimum of technical education will gradually be provided for, but the even more fundamental general education is still in a sad plight. Only a few universities have thus far been in a position to demand graduation from a high school or similar preparation as a prerequisite for a course in pharmacy.

In like manner as the pharmaceutical faculties have organized for conference, so the state boards have organized a National Association of Boards of Pharmacy. Much good in the way of harmonizing ideas and even requirements has already been accomplished. So long, however, as these boards are composed exclusively, or well-nigh so, of retail druggists, much progress cannot be expected. The several boards of pharmacy, medicine, health, etc., of a given state will have to be reorganized into one board of health and sanitation, on which pharmacy is represented, before any radical change can be expected.

Yet in spite of this rather unfavorable state of affairs progress is being made. While the grandeur of buildings, not infrequently burdened by a heavy debt, is the most striking outward sign, more subtle forces for advancement are at work. In 1892 the University of Wisconsin for the first time offered a four-years' course, on a par with the regular college course, leading to a bachelor's degree. Since then a number of other universities have

followed. Thus, a very different ideal is being held up to the pharmacy student. Even graduate work is being done.

With the older colleges, the school work was and still is supplementary to the training received by the apprentice in a drug store. At first certificates of attendance upon lectures were given, later the degree of graduate in pharmacy was conferred. The University of Michigan early followed English practice and gives the degree of pharmaceutical chemist. Some institutions also gave the degree of bachelor of pharmacy. A number of the eastern institutions now give the degree of doctor of pharmacy. The University of Michigan first broke away from the drug store experience requirement for graduation. Even the older colleges of the East now offer courses and degrees to those who have not had such experience, but this is not the rule. In many of the colleges of pharmacy of the larger cities, the college work is so arranged that the student can spend more than one half of his time in the drug store while attending college. All of the colleges belonging to the Conference, however, have abandoned evening instruction, though to a large extent they still maintain the character of a *Fortbildungs-Anstalt*.

Germany.—In Germany a compromise system also exists, but on a much higher plane. The apprentice must have passed the *Ein-jährig Freiwilligen Examen*, i.e. he must have passed the *Unter-Sekunda* of the Gymnasium. After an apprenticeship of three years he takes the assistants' examination before a local board. After three years as assistant he goes to the university for four semesters and then presents himself to the state board, consisting mostly of university professors, with one or more *Apotheker*. Not a few German pharmacists, however, have completed the entire course of the Gymnasium, have continued their university studies after the *Staatsexamen*, and have taken the degree of Ph. D.

France.—While Germany recognizes a second class of pharmaceutical practitioners, viz. the *Drogist*, France has abolished its second-class pharmacists as well as the former herbalist, and now recognizes but one class, viz. the pharmacist of the first class. Although the apprenticeship still plays a rôle in the education of the French pharmacist, only such pharmacies may now accept apprentices as are licensed for this purpose by the Superior School of Pharmacy. The Paris school is a part of the University of Paris and gives a three years' course for *pharmaciens*, and four years for *pharmaciens supérieurs*. Like many a German *Apotheker*, so not a few French *pharmaciens à première classe* continue their university studies for the degree of doctor of pharmacy, which in France is in every way the equivalent of the degree of doctor of philosophy. (See FRANCE, EDUCATION IN, under HIGHER EDUCATION.)

England.—As already indicated, in England the examination of the Chemist and Druggist has been the special privilege of the Pharmaceutical Society of Great Britain since 1868. This society maintains a school in Bloomsbury Square. Still, most of the candidates for this diploma attend other schools. The course for the Chemist and Druggist at Bloomsbury Square covers one year. A second year is offered for those who aspire to the honors of Pharmaceutical Chemist. A movement is on foot to improve the educational status of the British pharmacist. One suggestion looks toward the establishment of a five-year curriculum, or more correctly an apprenticeship of five years, supplemented by systematic science courses in the technical schools conducted by the county committees or boards. So long as the education of the future pharmacist is a special privilege rather than a public duty, no fundamental reforms can be expected. Recently some of the newer universities have taken up the subject of pharmaceutical education neglected by the older ones. With these may rest the higher development of pharmaceutical education in Great Britain.

Other Countries.—In Austria, Switzerland, and the Scandinavian countries, also in Russia, pharmaceutical education follows, more or less, along German lines. The other Romance countries follow France to the extent of their ability. E. K.

PHELPS, ALMIRA HART LINCOLN (1793-1884).—Pioneer in the movement for the higher education of women and author of many science textbooks; was educated in the Berlin (Conn.) Academy and studied botany, geology, and chemistry privately under Professor Amos Eaton (q.v.) of the

Rensselaer Polytechnic Institute at Troy. She taught in the district schools of Connecticut, was instructor of science in academies at Berlin, Conn., Pittsfield, Mass., and Sandy Hill, N.Y. For several years she was an instructor in the Female Institute at Troy, N.Y., conducted by her sister, Mrs. Emma Willard (*q.v.*). She was later principal of a school at West Chester, Pa., and her last work was as principal of the Patapasco Institute at Ellicott's Mill, Md., where she trained many distinguished women teachers. She was an ardent advocate of the scientific *vs.* the classical and literary education for women; and she was the second woman (Professor Maria Mitchell was the first) to be elected to membership in the American Association for the Advancement of Science (*q.v.*). Her publications are numerous; *Lectures on Botany* (1828), *Dictionary of Chemistry* (1829), *Botany for Beginners* (1833), *Female Student* (1833), *Geology for Beginners* (1834), *Chemistry for Beginners* (1835), *Lectures on Natural Philosophy* (1836), *Natural Philosophy for Beginners* (1836), *Lectures on Chemistry* (1837), and *Hours with my Pupils* (1858). With her sister, Mrs. Willard, she translated from the French (1834) Mme. Necker de Saussure's (*q.v.*) *Progressive Education*. She wrote many papers on the higher education of women, several of which were translated into French; and she was active in the American Association for the Advancement of Education (*q.v.*).

PHENOMENALISM.—A name given to two different types of philosophy. According to one theory, what we know is simply the appearances of real things, these appearances consisting of the impressions which they make upon the mind. This view includes within itself many philosophies otherwise diverse from one another. Kantian phenomenalism, for example, is distinguished by the emphasis which it lays upon the synthetic activity of *a priori* powers of the mind in transforming passive impressions into objects concerning which universal judgments are possible. Spencerian phenomenalism emphasizes the fact that the unknowable things-in-themselves have gradually molded the mind, through heredity, in the long-continued evolutionary process, so that the impressions made upon it arrange themselves in modes which somehow parallel the relations of things-in-themselves. The other type of phenomenalism is radical. It holds that there are no things-in-themselves back of the phenomena and causing them, but things are what they are known to be. Shadworth Hodgson in England and Renouvier in France are the best known modern representatives of this kind of phenomenalism. Its

influence in developing the radical empiricism of James was considerable. J. D.

PHILADELPHIA CENTENNIAL EXPOSITION.—See EXPOSITIONS, INTERNATIONAL, AND EDUCATION.

PHILADELPHIA, CITY OF.—The chief city in the state of Pennsylvania, and the third city in size in the United States. Its population in 1910 was 1,549,008, which was about one fifth of the total population of the state.

Educational History.—The colonial history of education in Philadelphia has been traced, under the history of education in the state of Pennsylvania (*q.v.*). Private and denominational schools were established from time to time, and these supplied the educational needs of the city until the nineteenth century.

The state laws of 1802 and 1809 provided for the organization of pauper schools, but not much was accomplished in the city under it. Under a supplement to the 1809 law, secured in 1812, the county commissioners and the councils were enabled to organize a few schools. In 1814 the "Pennsylvania Society for the Promotion of Public Economy" was organized, with Roberts Vaux as chairman of the subcommittee on public schools. In 1817 a number of schools after the Lancasterian plan were opened in Philadelphia, and in 1818, as an outcome of agitation, the legislature organized the county of Philadelphia as the First School District of Pennsylvania, and provided for the education of the children of the city at public expense. The city was divided into school districts; directors were appointed, one for each section, to be known as the Board of School Controllers. The beginnings of the dual control, which so long continued, were here made by giving the appointment of teachers to the directors for each section. The schools were open only to indigents. A model school, under Joseph Lancaster himself, was opened in 1818 for the training of teachers. In 1827-1828 three Infant School Societies were organized in Philadelphia, and by 1830 some ten such schools were in existence in the city. In 1832 the Controllers opened an Infant Model School for the training of teachers for the Infant Schools, and in 1837 thirty primary schools, under the charge of women teachers, were established as a result of the movement. The model school lapsed and became a grammar school after four years, and the real city normal school was not established until 1848.

In 1827 "The Society for the Promotion of Public Schools" was organized, and this Society undertook to agitate for a better public school law. The state law of 1834, establishing a general system of common schools (see PENNSYLVANIA, STATE OF), was in part the result of the work of this Society. The revised law of 1836, which really estab-

lished the system, contained two provisions of special interest to the city of Philadelphia. By the first, the Board of Controllers of the Public Schools were authorized to establish a central high school, and by the second, the obligatory use of the Lancasterian system and the limitation of the schools to indigents were withdrawn. The central high school was opened in 1838. This was followed, in 1848, by the establishment of the Girls' High and Normal School, the first city normal school in the United States.

In 1854 the Consolidation Act combined the city and county of Philadelphia, and annexed a number of suburban towns. For each of these a new sectional board was created, and local or sectional interest now attained new importance. Gradually increasing with the growth of the city, there were 31 sectional boards with 403 members by 1880, 34 sectional boards with 455 members by 1889, 41 sectional boards with 533 members by 1900, and 43 sectional boards with 559 members by 1905. In that year the law was revised; the old Board was legislated out of office, a Board of Education of 21, appointed from the city at large by the judges, took their place, and the local boards, while continued, had their powers materially curtailed. The new Pennsylvania school code of 1911 made still further changes.

Present School System—The control of the schools of the city is vested in a Board of Public Education of fifteen, appointed by the Judges of the Court of Common Pleas of the city, and for six-year terms. One third go out of office each biennium. For each of the municipal wards of the city a Board of School Visitors of seven members is elected, for four-year terms, approximately one half going out of office each biennium. The members of these Boards of School Visitors are paid \$25 (formerly \$100) a year, are required to visit the schools every three months and inspect them, and to make reports as to their inspection and as to the needs of their district to the Board of Public Education. They may also appoint the janitors for the elementary schools of their ward. The City Controller is elected as controller for the Board of Education, and approves all orders on the school treasurer, certifies to all contracts made, and keeps a record of the budget and funds of the Board. A Secretary is elected from outside the Board, while the City Treasurer acts as treasurer for the Board. The Board also elects a Superintendent of Buildings, a Superintendent of Supplies, and a Superintendent of Schools. The Board of Education defines the general policies of the school system, enacts all necessary legislation, determines the tax levy and directs expenditures, appoints teachers and other employes, and determines the qualifications and salaries of all employes. The supervision of the school system is vested

in the Superintendent of Schools, the associate superintendents, and the assistant (or district) superintendents. The supervision of instruction is in the hands of the school principals and of the assistant superintendents. The Board may appoint a board of city examiners, on nomination of the Superintendent of Schools, to examine teachers for the city, and of this board the Superintendent is *ex officio* chairman. The Superintendent of Buildings must be an architect or an engineer, and he has charge of the building, repair, and maintenance of all school buildings. He appoints all of his assistants, and all janitors, except for the elementary ward schools, and may remove even these for cause. The Superintendent of Supplies makes all purchases of supplies and books, and attends to their distribution. The Board may levy an annual city tax of not less than five nor more than six mills, for all maintenance purposes. They may also issue bonds for sites, buildings, or debts, up to a total of 7 per cent of the assessed valuation of the city. If the school debt is less than 2 per cent, the Board may borrow money on notes, up to $\frac{1}{2}$ of 1 per cent. They may also designate any bank as a depository for the school funds.

The school system of the city contains a large number of different types of schools, adapting it to the needs of a large and cosmopolitan city. A city normal school, with a three-years' course beyond the high school; the central high school for boys, with a School of Pedagogy as an adjunct; two high schools for girls, one of which is a vocational high school; three manual training high schools; one day and two evening trade schools; a number of district high schools, in part as branches of the above; evening high schools and trade-school classes in nearly all of the higher schools; a number of special disciplinary and special backward classes; day and evening elementary schools; evening schools for aliens; kindergartens; an industrial art school; many playgrounds; school gardens; open-air schools; public lectures; and much special instruction indicate the nature and extent of the city's school system. In 1910 the system required 4609 teachers and supervisory officers, and enrolled 175,549 pupils. The total value of all school property employed in 1910 was \$20,632,630, and the total expenditures for all purposes \$8,242,218.

PHILADELPHIA, INTERNATIONAL CONGRESS OF EDUCATION AT.—See INTERNATIONAL CONGRESSES OF EDUCATION.

PHILANTHROPINISM.—A movement which derived its name from the *Philanthropinum* established at Dessau by Basedow (*q.v.*), in 1774. The term denotes the humanitarian tendency which inspired the movement. Few educational institutions have had such immediate influence. The movement was strong enough to attract and hold the interest of men in all ranks of life and of divergent religions and philosophical views. The *Philanthropinum* was the first school which was established under the impulse given by Rousseau's *Émile*. It aimed to train up citizens of the world, men who recognized the community of interest among all human beings. Rich and poor boys were taught together; distinctions of religion were not recognized; manual and industrial work was introduced for social as much as educational reasons. The vernacular was emphasized as the medium of instruction. Things were placed before words, and if objects could not be obtained, pictures and illustrations were used. Grammar was given a secondary place and languages were taught by improved methods. Everything was done to make learning attractive and experience as broad as possible. Special attention was given to physical exercise, health, and diet. Among ardent supporters were Kant, Lessing, Moses Mendelssohn, Iselin, Von Rochow. But there were opponents, too; mainly the theologians and old teachers. Basedow himself was assisted by Wolke, Simon, Schweighäuser, Campe, Trapp, Salzmann. The *Philanthropinum* at Dessau continued from 1776 to 1793, but Basedow was not director throughout that period. Campe (*q.v.*) opened a similar institution at Trittow, near Hamburg, in 1777, and was succeeded in 1783 by Trapp (*q.v.*), who had been professor of pedagogy at Halle (1777–1783). In 1781 Salzmann (*q.v.*) established with the favor of Ernest II of Saxe-Gotha a *Philanthropinum* at Schnepfenthal which has continued to the present day. Outside Germany the influence of *Philanthropinism* was strongest in Switzerland. In 1774 Charles Ulysse de Salis transferred to his castle at Marschlin in Grisons a school which had been established in 1761 by Martin Planta. Karl Friedrich Bahrdt was placed in charge, but left in 1776 to open a *Philanthropinum* at Heidesheim. Another school of this type was opened by J. B. de Tschärner at Jenins in the same district and transferred to Reichenau in 1796 where it met with great success under H. Zschokke.

The Philanthropinistic movement was as influential as the Pestalozzian in drawing attention to existing defects in education and in leading to salutary reforms. A large body of literature was inspired by it; Campe's *Allgemeine Revision des gesamten Schul- und Erziehungswesens* in sixteen volumes, and his *Braunschweigischer Journal*, and Trapp's *Versuch einer Pädagogik* may be mentioned. In

another direction the new attitude to children led to a large number of books written for children by Campe, Salzmann, and others.

PHILANTHROPY, EDUCATIONAL.—

The custom of giving for educational purposes is one of long standing and of the greatest importance. It finds numerous illustrations in the classical period and, as connected with the church, became widespread and of fundamental significance during the late medieval centuries. Following the Reformation, there was a marked decline in this custom, but there were periods in English educational history wherein charitable gifts for education again became very general, first through the interest of dissenting bodies in developing higher educational interests of their own and later through the interest of the established church in building up an elementary school system, the so-called charity schools (*q.v.*). The entire historical phase of this topic of educational philanthropy is presented under the caption Endowments (*q.v.*). But it seems quite evident that the existence of an established church and the growth of state subsidized or supported school systems, first on the continent and later in England, has resulted in the atrophy of this significant social custom. In America, owing partly to the absence of an established church and, even when local or general governmental support of education became general, partly to the fact that such support awaited the initiative and cooperation of the people themselves, private philanthropy has played a very large part in the development of the entire educational system.

At present the extent of private philanthropy for educational purposes is one of the most significant phenomena in American life, and certainly when compared with conditions in other countries one of the most significant features of the educational system. In 1910 22 per cent of the entire income of the 602 universities, colleges, and technological schools reporting to the United States Commissioner of Education came by way of benefaction, in amounts ranging from sums of a few dollars to over a million; and over 52 per cent of these gifts was applied as permanent endowment funds. Five hundred and thirteen of these institutions are controlled by private corporations and eighty-nine by city, state, or nation. These facts alone point to the present significance of philanthropy in higher education in the United States.

Doubtless the same instinct, fundamental to group life in general, which prompts the humblest man to relieve his brother in distress, is finding here in man's higher intellectual aspirations a suitable interest for the bestowal of charity. The one type of giving is prompted by immediate needs, and seeks only to conserve; the other by remote needs, and looks toward progress. If the one is socially negative the other is as distinctly positive. And regardless of the theories of Turgot, Adam Smith, Hobhouse, and others, that the "dead hand" policy in education is inimical to progress (see *ENDOWMENTS*), yet, as will be seen in the following diagrams, gifts and bequests have played and are playing no small part in making our higher institutions of learning what they are. The following chart, including the 602 institutions referred to above, will indicate, so far as numbers of schools can indicate, the part which philanthropy has played in establishing colleges and universities from the beginning down to 1910.

The simple gifts of "sheep, cotton cloth worth nine shillings, a pewter flagon worth ten, and such silver goods as fruit dishes, silver spoons and jugs," recorded among Harvard's early receipts do not seem to foretell the millions in stocks, bonds, and real estate which are among her more recent gifts. From an analysis of gifts to educational institutions it is clear that relative to the total annual income, religious interest is on the decline, and scientific interest is increasing; that the qualifications of scholarship are replacing those of indigence, that it is a specific rather than a general educational interest which prompts the gift, and that the number of interests has increased correspondingly with the number of professions and callings that have gradually been opened to college graduates.

The following analysis of the gifts recorded in the *Appleton and International Yearbooks* and the *World's Almanac*—gifts of five thousand dollars and over, made during the years 1893 to 1910—will suggest the relation of

The early history of higher education is a very simple story, and the extremely local nature of our early foundations, such as Harvard and Yale, which were built for and by Massachusetts and Connecticut respectively, and for years developed according to their neighborhood interests, stands out in strong contrast to the recent foundations of Chicago and Stanford Universities, the Carnegie Institution, and the General Education Board, whose interests are at least national, and which are in no sense products of local causes and conditions. These tendencies seem to indicate that philanthropic interests and methods have kept pace with our rapid development in population, wealth, and business methods.

educational to other kinds of philanthropy in this country during recent years. As to form, it will be noticed that there is a slight tendency toward gifts rather than bequests; and that education is receiving more than half of all the gifts.

The actual importance of these gifts in the support of higher education is seen in the diagram on page 670, statistics for which were compiled from the annual *Reports of the United States Commissioner of Education*. As permanent endowment funds accumulate, naturally income from that source increases, consequently 22 per cent of the total income in 1910 means much more than a similar proportion in 1871. Statistics for the past few years

PHILANTHROPY, EDUCATIONAL

show that about 50 per cent. of all gifts to higher education are applied as permanent endowment, over 30 per cent goes to buildings and improvements, and less than 20 per cent for current expenses.

TOTAL BENEFACTIONS IN THE U.S.

Unlike England, philanthropy has had little to do with elementary education in this country during its early history, and save indirectly it has done little in later years. The Peabody Education Fund of \$3,000,000, established in 1867, was used during its first four years in starting city systems of public schools in towns and cities throughout the southern states, then to 1875 it was used to aid in the establishment of state systems of public schools. Its next work, 1875 to 1904, was to aid elementary education indirectly by the training of teachers and by establishing the idea of state normal schools throughout the south. The John F. Slater fund of \$1,000,000, established in 1882, is devoted to the training of colored children in industrial pursuits; the Anna T. Jeanes Foundation (1908) of \$1,000,000 is to be devoted to the fostering of negro rural schools; while the studies made by the Russell Sage

PHILANTHROPY, EDUCATIONAL

Foundation are indirectly devoted to this end. These are a few noteworthy cases in recent years but do not suggest the educational, social, and industrial problems which philanthropy sought to solve in England through the endowed, the charity, and the workhouse schools.

The problems of secondary education have received some attention. Most of the early

endowed and church colleges had preparatory departments, and many such are still maintained. The history of the academy move-

ment is to a large extent the history of private munificence in an effort to solve some of the problems of secondary education. The work of the General Education Board (1902) was, up to 1905, devoted to secondary, rural, and negro education in the southern states, and

new era in respect to the size of gifts, but he attached no religious or ecclesiastical condition to his gift. The only conditions governing its administration are general in character, and adequate provision is made for further modifications as social and educational changes seem to warrant. Since this foundation there have been established six others — the John F. Slater Fund, the Carnegie Institution, the General Education Board, The Carnegie Foundation for the Advancement of Teaching, the Russell Sage Foundation, and the Annie T. Jeanes Foundation — ranging in amounts from one to over \$50,000,000, and in the provisions for the administration of these funds and their income the ideas of Mr. Peabody are embodied. Still more recently (1911) are the Rockefeller and the Carnegie Foundations chartered under special acts of the state of New York. (For the particular influence of each of the great founda-

tions upon American education, see articles under their respective heads.) J. B. S.

one of its present aims is the development of a system of public high schools in the south.

The experience of England which resulted in the establishment of government commissions for the investigation of the influence of the "dead hand" in education, and finally in 1869 in the Endowed Schools Act (*q.v.*) should have suggested to America the wisdom of accepting the aid of philanthropists in education with due precaution. The early gifts to Harvard, Yale, and Columbia were in large part direct to the college, leaving the Trustees to apply them as they saw fit. Yet the early Presidents of Yale several times complained that with all the money received, so much of it was given for the development of some particular, often some new, line of work that the college was very much in need of funds. A gift for a new wing to a hospital lays upon future benefactors the burden of its support. Many peculiar and too often unwise gifts have thus been made in the brief history of American philanthropy. Yet, if we take note of the modern methods in giving, there seems to be reason to believe that we are forestalling some of the misfortunes which befell the endowed schools of England. In 1867 George Peabody, probably through the assistance of Robert C. Winthrop of Boston, suggested a new and important idea in philanthropic methods. With him there not only began a

PHILANTHROPY, EDUCATIONAL ASPECTS OF MODERN.

— The earlier conceptions of charity regarded it chiefly from two aspects, neither of which related it to educational work. It was regarded first as a means of promoting the spiritual development of the donor, and second, as the distribution to unfortunates of a bounty, prompted by sentiment and not based on rational grounds. The bestowal of alms was an event which did not relate itself in any important way to the life history of the donor, or to that of the recipient. In the case of the donor it was a distribution of a surplus by methods having no relation to those by which the surplus was acquired. In the case of the recipient it dealt with the passing need which, presumably, no one could have foreseen, and which it was hoped would soon disappear through the operation of economic forces, or which, if permanent, would be cared for in an elementary way by the provisions of the poor law.

Later conceptions of charity try to rationalize the giving of relief of every nature; to relate it to the life history both of the donor and of the recipient; to take into account fully the facts, both social and individual, which have resulted in the condition of need; to

take into account all the important factors in the life of the recipient and not merely those lying on the surface; and to deal with present need with a view to future efficiency as well as to immediate relief. The donor also feels increasingly the need of making his benefactions square with all his other social relations. Not only must the left hand know what the right hand does, but it must be admitted frankly that one and the same mind directs both. These points of view having been met, the giving of charity in whatever form relates itself directly and in numerous aspects to the field of education. The following educational aspects of modern charity will be considered: (1) training the recipient in efficiency; (2) social work becoming a profession; (3) popular education, looking toward the removal of some of the individual causes of poverty; (4) research and agitation for legislative and administrative reforms; (5) education by conferences; (6) education by periodicals.

(1) The larger and truer view of the recipient of charity, taking into account not merely his condition of need at the moment, but his social relations and responsibilities, trying to understand his past and to safeguard his future, leads necessarily to considering whether his need is due to fault or to misfortune, and, if due to his fault, it points to an effort to revive, develop, or train whatever latent powers he may have, in order that he may become, if possible, a fully self-supporting economic unit. The educational development, especially of juvenile charges, the training of the adolescent in industry, and the development of the unused faculties on the part of the adult have become a part of all well-considered relief work.

(2) This conception of charity calls for a considerable degree of acumen and a high degree of efficiency on the part of those who are to administer it. It calls for specialization in work. Any one can pass out coins to beggars on the street, but only men of training and efficiency can so give relief as to increase the power of self-support and thus diminish the future need of relief. Until quite recently those who had been failures in some other line of work, or suffered from impaired health, or lack of tact, or want of energy, were regarded as clearly marked out for the position of almoner or relief agent. It is now evident that such persons cannot be considered competent to undertake the delicate, difficult, educational problem of modern charity. In the late eighties and the early nineties a considerable number of important charitable agencies in the larger cities began to look to the colleges and universities for trained men and women, not only as their chief executives, but also to fill the subordinate positions. At the International Congress on Philanthropy, held in Chicago in 1893, the writer presented a paper on benevolent work as a profession, calling

attention to the fact that charitable and correctional activities offered an attractive field which college and university men were just beginning to appreciate. From about that time the number of well-trained men and women who chose the field of social work as a career rapidly increased. As a result the work of the agencies choosing such executives became much more vital and stimulating, attracted much more attention from the communities in which they were placed, and brought into the field of discussion and action many matters of civic, economic, social, and political interest having a direct bearing upon the condition, needs, or relief of the poor.

It had now become evident, however, that the graduate of a college or university still lacked much in the way of preparation. The Charity Organization Society of New York City led the way in a further departure, the establishment of a school for the training of social workers. This school, organized as a summer course in 1898, developed into a course extending through the usual school year in 1903-1904, and was greatly strengthened by an endowment of a quarter of a million dollars from the late John S. Kennedy in 1904, which was increased to a million dollars by a legacy from Mr. Kennedy, received in 1910.

Similar institutions have since been established in Chicago, Boston, St. Louis, and Philadelphia. The School for Social Workers in Boston was established in 1903 under the joint auspices of Harvard University and Simmons College. The Chicago School of Civics and Philanthropy, established in 1903, and the St. Louis School of Social Economy, established in 1901, are not directly connected with other educational institutions, but are carried on in each case by groups of persons closely identified with the leading agencies for social betterment. The Philadelphia Training School for Social Work was established largely by those interested in child-caring work in that city. All four of these institutions are rapidly becoming fully developed professional schools, and social work is rapidly gaining recognition as a trained profession.

(3) From the study of the best methods of relieving individuals and families, the trained social worker naturally passed on to consider the possibility of ascertaining and of restraining some, at least, of the great causes of poverty. The development of medical and social sciences has given new and most important information as to the relations of disease to poverty, and new and most valuable weapons for the conquest of disease. The first society for the prevention of tuberculosis in the United States, that in Pennsylvania, was an independent organization. The second organized effort for the prevention of tuberculosis, and perhaps the most effective and far-reaching agency of the kind in existence,

is the Committee on the Prevention of Tuberculosis appointed by the Charity Organization Society of the City of New York in 1902. The campaign for the prevention of tuberculosis in the state of New York, outside of New York City, has been carried on by the State Charities Aid Association, which was organized in 1872 for the special purpose of securing the improvement of the condition of public charitable institutions and the administration of public relief. The National Association for the Study and Prevention of Tuberculosis was composed at the outset largely of physicians, but included also a group of active and effective representatives of social work. It is generally the case throughout the United States that state and municipal campaigns for the prevention of tuberculosis are either carried on by committees appointed by charitable or relief societies, or that the active workers in independent agencies for the prevention of tuberculosis are drawn from the ranks of those who have been active in charitable work. These campaigns for the prevention of tuberculosis are, however, now primarily educational. The tuberculosis exhibition, with its accompanying publicity, popular leaflet and popular lecture is practically a new departure in popular education.

The effectiveness of the exhibition as a factor in popular education has been developed by charitable agencies more strongly than by any other group. A tenement house exhibition, organized by the Charity Organization Society, was the first step in a series of events which led to the creation of a tenement house department in the government of New York City. The State Charities Aid Association, in prosecuting its movement for the prevention of tuberculosis, has sent popular exhibitions to the county fairs throughout the state of New York, and to the State Fair. Plans are already in hand for the utilization by charitable agencies of this same form of popular education for restraining other great causes of poverty. The relation of intemperance and of immorality to disease, insanity, blindness, and other misfortunes is likely in the near future to be brought home to people generally by charitable agencies, in a manner which bids fair to be far more convincing than any other presentation of the arguments for right and simple living.

(4) In their search for the causes of poverty and in their efforts to control such causes, charitable agencies have, in a number of instances, taken the lead in informing and arousing popular sentiment as to the need of new forms of administration and in securing legislation for such changes in administration. The search for the causes of poverty, emphasizing in certain aspects the responsibility of the individual, has nevertheless done its chief service in pointing out the direct relation between certain social conditions, legislation,

and administration and poverty. The movement to secure better legislation in the matter of employers' liability in a number of states has gained its chief impetus directly from inquiries set on foot by social workers. The Pittsburgh Survey, undertaken by *Charities*, now *The Survey*, which, in turn, is a department of the Charity Organization Society of the City of New York, is probably the most widely known, as it is perhaps the most comprehensive and far-reaching effort to give a concrete description of the actual conditions of life and work in an American city, in such form as to disclose the responsibilities of the various factors in the community for conditions affecting health and life, and the directions in which municipal administration, legislation, and conscientious employers should move.

(5) The development of the professional spirit among social workers led naturally to a desire for an exchange of experiences and views, and for the discussion from time to time of problems of common interest. What is now known as the National Conference of Charities and Correction came into existence in 1874, through the agency of the American Social Science Association. The National Conference of Charities and Correction, while primarily a meeting place for the expression of opinion, and while it does not formulate platforms, nor suggest nor approve legislation, has become an educational factor of great importance. In the absence of any federal bureau or department dealing with questions of this nature, it has served to a considerable extent as a means by which active citizens in the different states have been informed in some degree as to legislation and administration in other states. It has tended to prevent excessive divergences in legislation or in policy as between different states, and has afforded at least an opportunity for advocates of varying systems to set forth their claims and to defend them. While the difficulties of securing anything like a harmonious development of social work in the different states under our federal system seem almost insurmountable, the National Conference of Charities has made a substantial contribution toward the development of a common body of knowledge and toward an interchange of experiences. More recently there has been developed in many states an annual state conference of charities and correction which, by enlisting the interest of local officials and agents of local societies, many of whom would not attend a national gathering at a considerable distance, has helped to spread the influence of the national body, to raise standards of work, to discourage easy satisfaction with traditional methods, and to make advanced legislation possible.

(6) Modern charity has to its credit the development, as part of its educational work, of a number of periodicals, several of which have merged in one, — *The Survey*, which ex-

erts a very substantial influence throughout the country. *The Charities Review*, established by the Charity Organization Society in 1891, under the editorship of Dr. John H. Finley, then secretary of the State Charities Aid Association, and now president of the City College of New York, after a period of ten years was merged in *Charities*, a weekly started by the same society, with which were subsequently merged the *Chicago Commons* and *Jewish Charities*.

It is perhaps not too much to say that in the course of the last four decades, charity, from being something incidental, irrational, unrelated to the main currents of social life, has become a thoroughly vital influence, addressing itself consciously and directly to the problems of social education and of political reform, as well as to the education of the individual.

PHILBRICK, JOHN DUDLEY (1818-1886).—City superintendent of schools; born at Deerfield, N.H., the 27th of May, 1818, and graduated from Dartmouth College in 1842. He was teacher in the high schools of Roxbury and Boston from 1842 to 1847 and principal of a grammar school at Quincy from 1847 to 1852. He was for two years principal of the State Normal School at New Britain, Conn., and two years state superintendent of the schools of Connecticut. In 1856 he was elected city superintendent of the schools of Boston, which position he held until 1878. He was special educational commissioner to the Vienna exposition of 1873 and director of the United States to the Paris exposition of 1878. He was also a member of the international jury of education at both these expositions. "He was the first American city superintendent of schools to win international distinction."

Mr. Philbrick's educational writings include *Truancy and Compulsory Education* (1862), *City School Systems in the United States* (1885), several addresses in the *Proceedings of the American Institute of Instruction*, articles in Buisson's *Dictionnaire de Pédagogie*, reports on the educational exhibits at Vienna in 1873 and Paris in 1878, *American Union Speaker*,

Primary Speaker, and reports on the schools of Boston. For several years he was editor of the *Connecticut Common School Journal* and the *Massachusetts Teacher*. He was prominently connected with the Connecticut Teachers' Association, the American Institute of Instruction, and the National Education Association (qq.v.), and held offices in all these associations. His report on the *Tenure of Office of Teachers* is a valuable educational document. W. S. M.

PHILIPPINE ISLANDS, EDUCATION IN THE.—Consists of islands and islets,

3141 in number, with a total area of 127,853 square miles and a population in 1910 of 8,276,802. Formerly Spanish possessions, they were ceded to America in 1898. Manila is the capital.

Historical.—The Filipinos were not wholly illiterate before the arrival of their Spanish conquerors. The influence of the civilization of India had extended to Malaysia and modified the culture of the primitive forest-dwelling and seagoing Malays. Syllabic systems of writing were in use in the Philippines. Chirino (*Relación de las Islas Filipinas*, 1604) states, "So given are these islanders to reading and writing that there is hardly a man, and much less a woman, that does not read and write in letters peculiar to the island of Manila." "They write upon canes or the leaves of a palm, using for a pen a point of iron." These syllabaries passed quickly out of use among the peoples Christianized by the Spanish, and no actual examples have come down to us, though the form of the syllabaries has been preserved as used by Bisaya, Tagalog, Pampango, Pangasinan, and Ilokano. Similar syllabic forms of writing are still employed by the uncivilized Mangyan of Mindoro Island and the Tagbanwa of Palawan.

Mohammedanism had also entered the southern islands of the archipelago and sent colonists to Manila Bay. The entrance of this faith meant a new source of civilization, with writing in the Arabic characters, and books of laws, genealogies, and devotion. The Moro peoples of Mindanao and the Sulu Archipelago still maintain teachers and *imams*, while the proportion who can write their Moro languages in Arabic character is surprisingly large.

But the dominant influence in the civilization of the islands was destined to be European and Christian. The permanent occupation by Spain began with Legazpi's expedition in 1565. It was an American undertaking and it enjoyed the profit of three generations of

Spanish colonization in America. The Spanish conscience had revolted against the cruelty of the West Indies; Las Casas was still living in the monastery of his order at Valladolid; and the experience of years with the American Indian was available to guide the conqueror in his efforts to subdue and civilize the Malay.

The conquest was achieved with surprising rapidity and with little conflict. The "Indians," in accordance with the system in vogue in America, were given in *encomiendas* to the Spanish soldiery. Their numbers at this time were few, probably not over 600,000 in the portions of the islands subdued. There were no large settlements and few powerful chieftains other than the sultans of Magindanao and Sulu.

The spiritual conversion of the Filipinos was for a time delayed. A few Augustinian friars went out with the first conquerors, but, after more than a decade, Governor Sande wrote that there were only thirteen friars who could say mass, and he was not sure that any understood the language of the natives. A year later arrived a company of Franciscans; two Jesuits, shortly followed by others, came with the first bishop in 1581; the Dominicans arrived in 1587, and in 1606 the Recollects or unshod Augustinians. As late as 1594 the report of a friar relates that there were no missionaries on the islands of Leyte, Negros, Bohol, Samar, Mindanao, Masbate, or many other smaller islands where the natives had been under tribute for nearly a generation, but in that year the king of Spain began to provide generously toward the sending out of missionaries, and there were soon 300 scattered among the islands, the number rising to approximately 500 in the succeeding century.

These missionary friars gathered the Indians into towns or *reducciones*, built churches and parish houses or *conventos*, and organized the communities both civilly and religiously. By the middle of the eighteenth century they had the whole archipelago reduced to docility to Christian rite and practice, except the "Moro country," the mountain region of Northern Luzon, and the forested and mountainous interiors, inhabited by wild people.

Some attention was early given to educating the natives. The missionaries learned the diverse Malayan languages spoken in the Philippines, reduced them to written form, introduced the Roman alphabet, and early established printing offices where were published catechisms, books of doctrine and devotion, and grammars and vocabularies of the native tongues. In each *convento* it was usual to conduct a native school in the dialect, taught by the sacristan or some humble dependent of the church, where boys and girls of the town were prepared for communion and perhaps learned to write their native tongues. The teaching of Spanish was not attempted until late in the Spanish régime and was

opposed and condemned by the friars as likely to loosen the authority of Church and government.

Musical instruments were introduced for purposes of worship and recreation, and the astonishing aptitude of the Filipino in musical directions has made common in every village pianos, harps, violins, and the *bandúrria*. Organs are played in every church, and it is a poor town that has not a native orchestra and band.

The motives which led the Spaniards to establish secondary and high schools in the Philippines were the education of their own sons and training for the priesthood. The pioneer institution was the *Colégio de San José*, a college and seminary established by order of the king of Spain, opened in 1601. In 1610 it secured a bequest from the *encomendero* of Mindanao and from this endowment supported and educated from twenty to forty students (*becas*) for many decades. In 1644 it obtained by papal brief the right to grant degrees. A royal decree of 1722 recites that "the greater part of those who to-day obtain their prebends have been reared and prosecuted their studies in San José." In 1768 on the expulsion of the Jesuits it was confiscated, then erected into a school of medicine and pharmacy. Its possession became a subject of controversy that lasted to the close of Spanish authority and was revived under the American government.

In 1619 the Dominican order founded the College of Santo Tomas, which in 1645 by papal bull was made a university. A letter of the king in 1644 stated the desire to see it possess the same qualifications as the universities of Ávila, Pamplona, Lima, and Mexico. At this period it taught grammar, rhetoric, logic, philosophy, and scholastic and moral philosophy, had about thirty secular students, and bestowed the bachelor, licenciado, master, and doctor degrees. By decree of 1785 it received the title of "Real" and became known as the "Royal and Pontifical University of Saint Thomas Aquinas." The teaching of civil and canon law was added in the eighteenth century, and in 1875 courses in medicine and pharmacy. The "Moret Decree" in 1870 attempted to secularize this institution and bring it under government control as the "University of the Philippines," but the opposition of the Church prevented the enforcement of the decree. Since the American occupation it has reorganized and amplified its courses and is attended by large numbers of Filipino students, especially those seeking a training in law.

A number of other secondary schools, including *beaterios* for orphan girls, existed from an early date. The *Colégio de San Juan de Letran*, established about 1640 as a school for orphan boys, developed into a secondary school and, in charge of the Dominicans, be-

came a preparatory school to the University. It still exists and is largely attended.

At the beginning, these and similar institutions were not open to Filipinos, but during the eighteenth century the practice grew of ordaining native curates, and this opened the way for Filipino education. In 1800 five "concordial seminaries," one for each diocese, were opened to train native priests, and in 1862 they were placed in charge of the Paulist Fathers. The instruction at these seminaries was not adequate to prepare a trained clergy, and the curates became subject to harsh depreciation, especially after the opening of the Suez Canal (1869), when the numbers of the regular orders increased and antagonism developed between these Spanish missionaries and the Filipino priests (*clerigos*).

Up to and past the middle of the nineteenth century, education remained wholly in the hands of the Church, and while the mass of Filipinos received instruction in the parishes in doctrine and catechism, there were practically no educated Filipinos outside of the clergy. In spite of repeated decrees of the king enjoining the use and teaching of Spanish, this language had made no progress among the natives. Travelers in the islands up to 1870 are unanimous that the Filipinos able to speak the Spanish tongue were rarely met.

Meanwhile the increase of commerce, due to the opening of the archipelago and the production of hemp, sugar, and tobacco, largely in the hands of native families of local prominence, had produced a Filipino aristocracy with wealth and ambition. Knowledge of Spanish was a great distinction, and education for their sons was eagerly sought by men of means.

About 1862 began a movement of young men abroad for study. This practice continued, many being driven to study abroad because of the obstacles presented in the Philippines and the danger of being marked as a separatist or *filibustero*. At the end of Spanish rule some hundreds of young Filipinos had roamed the countries of Europe gratifying their curiosity and their thirst for knowledge. Many of these young men bore dramatic parts in the period of Revolution.

The education of the Filipino was greatly advanced by the return in 1859 of the Jesuits. In 1866 they established the Ateneo Municipal, a secondary school supported by the city of Manila, reorganized since the American occupation as a private college. In 1863 the Spanish government resolved to establish a system of public instruction. It was an important step in the Spanish program to reform and modernize the Philippine administration. The important decree of December 20, 1863, was issued by the colonial minister, José de la Concha. It decreed a normal school in Manila under the Jesuits; a school of primary instruction for boys and

one for girls in each town of the islands, the instruction to be gratuitous and attendance obligatory; expenses of the schools to be charged on the local budgets; school teachers to be exempt from the personal service tax and after five years' service to become "*principales*" or local aristocrats. Government clerical positions were to be filled by preference from the ranks of experienced teachers; a Superior Commission of Primary Instruction was to consist of the Civil Governor of the islands, the Archbishop of Manila, and seven others; the parish priests were to be "local inspectors" and direct instruction in Christian doctrine and morals. Fifty years ago so comprehensive a scheme of native enlightenment was more of a novelty in colonial administration than it would be to-day. Despite the defects and limitations of the plan, it must take place as a pioneer scheme in the modern education of backward peoples.

The plan thus inaugurated found slow realization; nevertheless, at the close of Spanish rule some 2100 schools were reported to be in operation, and most towns had buildings for boys and for girls. The teaching, however, was far from satisfactory, the methods poor, and the instruction was usually confined to the native dialect of the locality. In spite of these drawbacks, it is surprising how considerable a number of natives gained at least a slight knowledge of Spanish and the rudiments of education. Such was the educational situation when, in 1898, the Philippines passed from the sovereignty of Spain to the United States.

Present System.—The American army occupied Manila August 13, 1898, and on September 1 the public schools of the city were reopened. Little attempt was made at first to change the teaching or discipline, but American teachers were engaged to commence instruction in English. A year later, as the occupation of the islands advanced, schools were opened generally, army officers were charged with their oversight, and teaching of English was begun by enlisted men. Probably a thousand schools were in this way conducted by the army, even during the period of warfare. The Military Governor urged on the school work as a measure "calculated to pacify the people and to procure and expedite the restoration of tranquillity." These highly commendable efforts opened the way for the educational work established by the Philippine Commission.

The above Commission, under instructions from President McKinley to organize a civil government for the archipelago, reached the Philippines in June, 1900, and commenced its labors as a legislative body on September 1. Before reaching the islands, it engaged Dr. Fred W. Atkinson of Springfield, Mass., as a general superintendent of education. A broad survey of the educational needs was

made, qualified soldiers discharged from the volunteers were engaged as teachers, and new schools were opened with the cooperation of army officers.

On January 21, 1901, the Commission enacted an organic school law (Act 74, subsequently amended by act 477 and other acts) which centralized the administration of all public schools in a Bureau of Education. It was provided that instruction should be free and secular, that the English language should be the basis of instruction, that religious instruction might be given in public schools on certain days by priests or other qualified persons but not by teachers. The education of both sexes together, while not provided for by law, was assumed. A normal school and a trade school were authorized. Authority was given to the General Superintendent to engage 1000 American teachers and bring them to the islands, assigning them to towns where conditions were most favorable. These teachers were promptly secured, and by October, 1901, 765 were at work in nearly all parts of the islands. In 1902 the number increased to 926, the largest number ever at once in the field. This pioneer work was greatly embarrassed by difficulties of communication, disturbances due to bandits or *ladrones*, the disorganization of local government, upon which the maintenance of primary schools depended, and especially by a severe epidemic of cholera which swept over the archipelago in 1902-1903. In spite of extreme disadvantages, some 2000 schools were conducted, the naturalization of the English language was begun, and a considerable number of promising young people were brought under the personal influence of high-minded American teachers. These young natives were the nucleus of the new clerical and teaching force indispensable to the purposes of the government. Night schools for adults were early established in Manila and, proving popular, night classes were authorized and conducted by American teachers in many towns. They were gradually discontinued after 1904, except in Manila.

The first work was of a primary character, the aim being to lay a broad basis for popular enlightenment. But the demand for higher instruction in English was soon felt, and by Act 372 (March 6, 1902) secondary schools were authorized to give normal training, agriculture, and manual training, besides academic and commercial instruction.

At the end of 1902 Professor Bernard Moses, first Secretary of Public Instruction and Philippine Commissioner, resigned and was succeeded by General J. F. Smith. Dr. Atkinson resigned at the same time, and was succeeded by Dr. E. E. Bryan, Superintendent of the Normal School. He was followed in August, 1903, by Dr. D. P. Barrows, who had been for two years Chief of the Ethnological

Survey. Dr. Barrows continued at the head of school work until November, 1909, when he was succeeded by Mr. Frank R. White, who had entered the teaching service in 1901.

During 1903 and 1904 improved conditions made possible a rapid building up of school work and considerable improvement in administration. The administration is highly centralized. The Director of Education (formerly General Superintendent) appoints and promotes superintendents and teachers, prescribes the courses of study, authorizes the opening of new schools, selects and purchases all textbooks and supplies, which are furnished free to public school pupils, and approves building plans. The Director is responsible to the Secretary of Public Instruction, who is a member of the Commission and who has in his department five other bureaus besides Education. The number of division superintendents originally provided (ten) was inadequate, and the number was increased until one was appointed for each province. The provinces were divided into some 400 "districts," and an American teacher was designated as "supervisor" of each. Under these active men new primary schools were established, and many young Filipino teachers engaged and set to work. The aim was to extend the public school advantages to the people of the "barrios." This aim has been kept constantly in view and has been nearly realized.

The expenses of all instruction are divided between the insular, provincial, and municipal governments, the expenditures for 1911 being \$1,765,958, \$104,643, and \$1,258,230, respectively, a total of \$3,128,831.

Elementary Education.—In the school year ending March, 1909, 4194 primary schools were conducted and attended by no less than 570,502 pupils, about two fifths being girls. In 1904 the complete program of studies was issued. It represents a departure from American school curricula. It provides for three sorts of public schools, primary, 3 years (extended to four years in 1906); intermediate, three years; and secondary, four years. The subjects taught in the primary schools are reading, language, arithmetic, geography, hygiene and sanitation, municipal government, music, drawing, and industrial work. All instruction is in English, and all teaching at the present time in primary schools is done by Filipino teachers. Industrial teaching has received much emphasis. The Filipino is a dextrous and artistic worker. The varied and useful native manufactures, such as basketry, mat and hat braiding, were selected in 1904 for teaching in primary schools. Loom weaving, lace working, and embroidery have been added, and by the diffusion of these arts remunerative household occupations are being created and extended. Gardening is also taught as a primary school subject, and thereby new vegetables and food plants are introduced

into many parts of the islands. Since 1909, industrial teaching has been standardized, and nearly 400,000 pupils are now engaged in some sort of industrial work. The primary and intermediate textbooks have been written especially for Philippine schools and are models of good methods and of the publisher's art.

The intermediate schools were from the first vocational as well as academic. Six specialized intermediate courses were fixed upon in 1909; namely, general, teaching, farming, tool work, business, and housekeeping and household arts. There were 245 intermediate schools in 1911 attended by 25,000 pupils.

Secondary Education.—Secondary schools in 1904 were limited to one for each province. Comprehensive plans were framed for their development and the aid of provincial governments was secured for obtaining lands and buildings. These schools have become the intellectual centers of the provinces, and many possess large tracts of land for athletics and for farming, and groups of buildings including shops, domestic science buildings, and dormitories.

Attendance at all schools is voluntary. Compulsory attendance, though frequently urged, has never been authorized by law.

The school system is closely coordinated with the public service, and the examinations given by the Civil Service Bureau are taken by hundreds of intermediate and high school graduates who thereby become eligible for public appointment. The Bureau of Education has also provided courses of training for producing skilled assistants in several branches of the Government: nurses for the Bureau of Health, apprentice surveyors for the Bureau of Lands, and rangers for the Bureau of Forestry, besides training clerks, stenographers, and a teaching force of over 8000 men and women.

In 1903 the Government provided a plan of sending selected students to the United States. Some 209 have been appointed, usually for four years, but the plan has been discontinued, as University facilities have been provided in the Philippines.

Schoolhouses.—The rapid growth of the system of schools made necessary the use of hundreds of rude schoolhouses of native construction, but notable progress is now being made in erecting permanent school buildings of concrete. The first Philippine legislature, on its organization in 1907, passed, as its first act, a bill providing \$500,000 for barrio school buildings. It has since duplicated this sum. There have been other important insular appropriations for school buildings and numerous private donations.

Athletics.—A most important part of school work is athletics. American sports are coming to exert great physical and moral

influence. Field meets are held in all provinces, and there are four interprovincial meets, besides the insular meet at the annual carnival in Manila. In 1911, 482 competing baseball teams played 1201 official games, while a single province had 110 organized school teams. Basket ball is played by girls.

Teachers.—From the beginning great attention has been given to training the native teacher, without whom education must have continued on narrow lines and without a permanent foothold. This is accomplished by "training classes" conducted by the supervisors for their corps of primary teachers, by "vacation normal schools" held in each province for four weeks each year, and by "vacation assemblies" at Manila and a few other important places. Correspondence courses for teachers are conducted by the central office of the bureau. All native teachers are carefully graded in respect to attainments, and encouraged to keep constantly advancing.

The American teachers, who now amount to over 700, come from all parts of the United States. Those first appointed in 1901-1902 were selected by the General Superintendent without examination test. In 1903 some 125 were selected, under authority of the Civil Governor, by the Catholic Church in the United States. Since that date all appointments have been under the civil service of the islands, and eligibility is obtainable only by passing examinations. There is an agent in the United States for meeting prospective teachers, and the Bureau of Insular Affairs at Washington gives assistance. Each year an average of 100 new teachers, mostly men, are appointed. A vacation assembly for American teachers was established at Baguio, the summer capital, in 1908. The region is a cool, elevated plateau covered with pines. Courses are given by lecturers from American Universities and conferences on school work are held.

Special Schools.—There are several "insular schools." The Normal School at Manila provides an advanced course for training teachers and, previous to the opening of the university, prepared pupils for college, medical studies, and study of the law. The trade school at Manila is equipped for teaching mechanical drawing, woodwork, machine shop, motor repair, wheelwrighting, wood carving, ceramics, textiles, and minor industries. In addition to this central trade school, each provincial secondary school has woodworking shops and a mechanical drawing department, while several have machine shops also. Altogether 358 manual training shops in the schools are reported. In Manila are also a higher School of Commerce and the School for the Deaf and Blind. The Nautical School inherited from the Spanish régime was closed in 1907.

Results.—The results of this wide attempt

at education are becoming manifest. English is spoken by young people and children in practically every village, and the door to useful and enlightened life has been opened to thousands of young men and women. The Bureau aims to abolish illiteracy and give the entire population the basis of an education. If the present efforts are sustained, this end will be nearly attained for the youthful population in the course of another decade.

The school effort among non-Christian peoples, numbering about one million, is not as extensive, but significant results have been secured. Central schools, with provision for boarding pupils, are placed at the largest centers of the pagan population and an industrial and literary education is given. Such are the Igorot schools in the Mountain Province of Luzon, schools for Ifugao and Ibilao in Nueva Vizcaya, for the Bukidnon and Manobo on the Island of Mindanao and for the Tagbanwa of Palawan. Over 12,000 pagan children are being thus educated.

The schools of the Moro Province are not under the Bureau of Education, but are conducted by a superintendent who is an official of that government. Mohammedan prejudice and opposition have hindered the development of schools among these peoples, but some sixty schools are conducted, including a secondary school at Samboanga.

Higher Education.—The Philippine Legislature by Act of June 18, 1908, established the University of the Philippines. It is a corporation composed of six *ex officio* and five appointed members called "regents." The following colleges have been established: Medicine, organized in 1906, Liberal Arts, Agriculture, Veterinary Science, Engineering, Law, and Fine Arts. The College of Agriculture is located at Los Baños, Laguna Province; the other colleges are at Manila. These colleges, except Fine Arts, receive only graduates of high or secondary schools. The College of Liberal Arts is divided into the junior college, bachelor degree, two years, and senior college, master degree, three additional years. The other University courses are from three to five years' duration. The six colleges were attended during the school year 1911-1912 by 599 students, the School of Fine Arts by 801 students.

The freedom of instruction made possible by American sovereignty has resulted in a large increase in private institutions and the general prosperity of such schools. In 1902 the Liceo de Manila was established, almost the first Philippine secondary school under secular management. Many of the provincial towns now have private secondary schools. Until recently their courses of study were modeled after that of San Juan de Letran, the Ateneo, or other Spanish schools, and embraced no more than five years, following the primary school of three or four years. The bachelor's

degree was conferred. The desirability of raising the standard of secondary work in all these institutions being clear, the Secretary of Public Instruction began in 1908 to urge such reforms, promising therefor government recognition of their degrees. In 1910 a special examiner was appointed. All together seven institutions, not including Santo Tomas, have had their bachelor degrees recognized. These are Ateneo, San Juan de Letran, San Beda, Assumption College (women) in Manila, Silliman Institute at Dumaguete, San Vicente de Ferrer, near Iloilo, and the Colegio Seminario at Bigan, Ilokos Sur. PHILLIPS ACADEMY, ANDOVER, MASS.

—Founded in 1778 by Samuel Phillips (*q.v.*), then Lieutenant Governor of the commonwealth. It was designed to prepare boys for the higher institutions and to fit them for the largest civic usefulness. The school, which was founded on broad democratic lines, early acquired a national reputation and prestige. It was visited by President Washington, who later sent nine of his nephews and grand-nephews to enjoy its benefits. The Academy was incorporated in the last act of the "Great and General Court" just prior to the formation of the new state government. Phillips Academy has grown steadily in numbers, in material equipment, in efficiency and influence. Its enrollment in 1911-1912 was 571 boys. Its equipment consists of 35 buildings. Its faculty numbers thirty-three men. Its students come from practically every state in the Union, and from many foreign countries, and its graduates are accustomed to enter annually a score or more of the higher institutions of learning. The school prides itself on its democracy, boys who are compelled to work their way mingling and competing on equal terms with those of generous wealth.

PHILLIPS ACADEMY, EXETER, N. H.

—Founded in 1781 by John Phillips (*q.v.*), the chief benefactor of the institution for the purpose of "promoting Piety and Virtue, and for the education of Youth, etc." William

Woodbridge (*q.v.*) was the first principal. Instruction is offered in all the studies required for admission to the leading colleges and scientific schools. By the constitution of John Phillips the academy is "equally open to youth of requisite qualifications from every quarter." The school enjoys a great reputation throughout the country and trains students from all parts of the Union. The students are divided into four classes or years. The enrollment in 1911-1912 was 522, and the faculty consisted of twenty-six members. The equipment has been gradually augmented, more particularly since 1883. The students are distributed in a number of dormitories, and throughout their stay in the school are under the charge of advisers whom they consult on matters relating to studies and school life.

PHILLIPS, JOHN (1719-1795).—Founder of Phillips Academy at Exeter; born at Andover. He graduated from Harvard University in 1735 and for a time taught school. He had some idea of entering the ministry, but decided finally on a mercantile career at Exeter. When his nephew, Samuel Phillips (*q.v.*), founded Phillips Academy at Andover (*q.v.*), he contributed to its endowment. Probably influenced by his nephew, he founded Phillips Academy at Exeter in 1783, of which he was the chief benefactor. Phillips was for twenty years a trustee of Dartmouth College, where he endowed a professorship, and was also interested in Princeton College, to which he made some donations.

See ACADEMY.

PHILLIPS, SAMUEL (1752-1802).—Founder of Phillips Academy at Andover (*q.v.*); born at Andover. He was educated at Dummer Academy and Harvard University, where he graduated in 1771. Two years later he became town clerk and treasurer of Andover. From 1775 to 1779 he was a member of the Provincial Congress, and later of the senate, of which he was president in 1785. In 1801 he was lieutenant governor. From 1782 to 1798 he was judge of the common pleas in Essex County. He was greatly interested in education, was an overseer of Harvard University, and frequently visited the Andover common schools. He was the founder in 1777 of Phillips Academy (*q.v.*) in his native town and was largely instrumental in securing its endowment. See ACADEMY.

PHILO JUDÆUS (20 B.C.-c. 40 A.D.).—Hebrew philosopher, a native of Alexandria, Egypt.—See NEO-PLATONISM; MYSTICISM; also JEWISH EDUCATION.

PHILOLOGY.—The meaning of the term philology has been different at various times. Historically there are three main periods in which philological studies have flourished, (a) the Classical, (b) the Renaissance, and (c) the Modern period.

Classical Period.—The earliest use of the word *φιλολογία* is found in Plato, where it has the meaning "lover of dialectic," or "of scientific argument."† The corresponding adjective, *φιλόλογος*, bears the sense of "lover of discourse" in contrast to *μισόλογος*, "hater of discourse." The former adjective is used of Athens as a city "fond of conversation," as opposed to Sparta and Crete, according to tradition places where brevity of speech was more highly regarded (Sandys, Vol. I, p. 4; cf. Acts XVII, 21). In general use, however, the word bore a broad significance, both in Greek and in the Latin uses of the word which the Romans derived from the Greeks. In Cicero's letters the word *philologus* means merely "learned" or "literary." In the post-classic poem of Martianus Capella, *De Nuptiis Philologiae et Mercurii*, Jupiter at a meeting of the gods demands the rights of naturalization for one who has hitherto been only a mortal virgin, i.e. Philology, the bride of Mercury, who represents wisdom or knowledge. Philology is the goddess of speech or expression, and she is attended by seven bridesmaids, who are none other than the seven divisions of the quadrivium and trivium. The conception of philology which the poem presents is therefore that of systematic learning and its expression in speech or writing. From these uses of the term, it is apparent that *philologus* in Latin and in Greek was a word of both wider and less definite significance than it is in modern usage.

For other and more special aspects of the activity of the philological student, according to the modern understanding of the term, the Greeks and Romans employed two other terms, *γραμματικός*, *grammaticus*, and *κριτικός*, *criticus*. The first of these terms was used chiefly in the Alexandrian period, and like philology, its meaning was broad. It signified generally "student of literature," particularly poetic literature. The kind of study implied by the term is indicated in the six divisions of the subject given by Dionysius Thrax (c. 166 B.C.), in "the earliest treatise on grammar now extant" (Sandys, Vol. I, p. 8). These six parts are (1) accurate reading; (2) explanation of poetic figures of speech; (3) exposition of rare words and of subject matter; (4) etymology; (5) statement of regular grammatical forms; (6) the criticism of poetry. By criticism is meant the attempt to detect

spurious passages or spurious works. The grammarian was one, therefore, who busied himself with the study, the editing, as it would be called in modern times, and the interpretation of poetry. Criticism was the highest function of the grammarian. There were special reasons why the study of grammar and criticism (i.e. "the higher criticism") should be cultivated in the Alexandrian period. The work of the Alexandrian scholar consisted mainly in the classification of works, the determination of their authorship, the establishment of pure texts, the study of grammar in the narrower sense in order to determine the relative authority of different manuscript readings, and matters similar to these. A typical Alexandrian scholar was Eratosthenes (c. 276-c. 196 B.C.), a versatile man, and the first of the Alexandrians to assume the name *φιλόλογος*. He wrote treatises on geography, mathematics, astronomy, and chronology. His greatest work was one on the Old Attic Comedy *περὶ τῆς ἀρχαίας κωμῳδίας*, really a series of monographs on questions of authorship, date, textual criticism, language, etc., in the plays. But he was also a man of literary taste, and himself wrote poems and philosophical prose treatises. On the whole, the Alexandrian conception of philology may be defined as a combination of scholarship and literary versatility.

Besides the three groups of linguistic students represented by the *philologus*, the *grammaticus*, and the *criticus*, in classical times, notice must also be taken of the *philosophus* and of his attitude towards speech and language. The *philosophus* differed from the other three in that he sought for first principles, for the explanations of things, whereas the *philologus*, *grammaticus*, and *criticus* were concerned with specific pieces of literature or with individual phenomena of language. In his search for first causes, the *philosophus* was naturally brought to consider the nature of speech, its origin, and the relation of speech to thought and to the world of concrete objects. These questions were considered by the early Greek philosophers in great detail, some of Plato's most careful thought being given to them. In many respects the linguistic speculations of the philosophers entered the special province of the philologists, as, for example, the philosophers' study of etymology in the endeavor to determine the true meanings of words.

From this brief survey, it will be seen that the classical period never arrived at any unified or, on the whole, any very profound conception of the philological study of language and literature. It attempted to some extent to answer philosophically the question of the origin and nature of language, to interpret and correct the body of its traditional literature, and to a more considerable extent to work out a system of grammatical classifica-

tion and nomenclature. There was, however, no sense of the homogeneity of linguistic and literary studies and there was but slight sense of historical growth and development. On the side of attainment, encyclopedic learning was the ideal. Modern scholarship, in the development of a theory of philology, does not build therefore upon a classical basis. Classical thought on matters linguistic is not introductory to the modern science, but is more important for logic and philosophy than it is for linguistics. The most important linguistic inheritance of the modern period from classical times is to be found in the classifications and terminology of descriptive grammar. These have come down from Plato and Aristotle and the classic grammarians in unbroken transmission.

Medieval and Renaissance Periods — The neglect of classical literature in the medieval period implied the decadence of classical scholarship and philology. The extent of this neglect and decay may be inferred from the fact that knowledge of the classic idiom of Latin (and still more of Greek) was so imperfect as to give rise to a new form of the language so different from classic Latin as to require a new name for itself, — middle or medieval Latin. (See MIDDLE AGES, EDUCATION IN). The medieval period was not curious about philosophical or psychological questions concerned with language. It accepted mainly the story of the creation of language by Adam, and hampered by the flat chronology which prevailed, and lacking any clear sense of historical perspective, it was naturally not concerned with questions of change and development. The medieval period was incapable of adding anything to classical theories of the study of language and literature. At its best it was conservative, and even this function was very inadequately performed. A typical scholar of the best type in the medieval period was the English monk, Bede (*q.v.*). His study of language specifically was entirely practical, and he developed a free, clear, and harmonious Latin style which enables one to read his works with pleasure.

The Renaissance conception of philology is closely bound up with the general movements in thought and culture which deeply affected the life of Europe in the fourteenth and several succeeding centuries. The scholarship of this time was largely a revolt against scholasticism, with its exaggerated sense of the importance of dialectic in all matters concerned with the intellectual life. The Renaissance may be regarded mainly as a humanistic movement, and the study of literature was approached from the æsthetic rather than the intellectual side. Of great importance in the development of Renaissance humanistic studies was the restoration of Greek to its proper place as a learned language, and also the development of

a feeling for the purity of classical Latin idiom and a respect for it which was unknown to the medieval world. Language was studied, however, almost exclusively as an approach to literature. The philosophy of the Renaissance linguists never concerned itself with any questions deeper than that of the relation of a learned to a popular language, as in Dante's *De vulgari eloquio*, and with the consequent question, how a popular language can be elevated to a position on a level with the learned languages. Language and grammar were regarded as handmaidens to literature, and the main purposes of the study of literature were partly higher criticism and partly appreciation but, most of all, imitation. Excellence in literature was to be attained by the imitation of classic models, and the first thing necessary was naturally a knowledge of classic types of literary art. As aids in attaining this knowledge, the Renaissance scholar gave much attention to the writing of grammars, dictionaries, and helps to composition. His persistence and enthusiasm have been effectively and truly presented in Browning's poem, *The Grammarian's Funeral*. So great was the respect which the Renaissance student felt for the classics that language alone was often regarded as sufficient to make a humanist. It was enough, many humanists thought, if one imitated exactly the language of Vergil, or Ovid, or above all, Cicero, regarded by almost universal consent in the Renaissance as the perfect model of eloquence. (See CICERO-NIANISM.) Nevertheless the scholarship of the Renaissance, though sometimes narrow and pedantic, in the hands of its best representatives was enlightened and astonishingly comprehensive. Among typical scholars may be mentioned the Frenchman Budé, or Budaeus (1468-1540), who speaks of philology as his *altera conjux*, and who also declares that he was the first to call himself a philologist (see Delaruelle, *Budé*, p. 215). Another famous Renaissance scholar was Joseph Justus Scaliger (*q.v.*), whose learning and productivity are indeed occasions for wonder. But the modern student is likely to feel with respect to Scaliger and with respect to Renaissance scholarship in general, that it is disorganized and often smothered under its own accumulation of detail.

Modern Period. — With the modern development in scholarship, attempts have been made to organize a system of philological study as clearly defined as are modern botany, biology, and astronomy. The beginnings of this movement, which has resulted in the formation of the theory of the science of philology, with clear delimitations of subject matter and of method, were in large measure, like the beginnings of Renaissance scholarship, a protest against the intellectualism of a preceding period. In Germany, where philology was earliest cultivated in modern times, it was at first closely connected with the neo-humanism and romanticism of the

latter half of the eighteenth century, which in turn were largely a reaction against the preceding and contemporary philosophy of the enlightenment (*q.v.*), with its contented but somewhat narrow *Aufklärung* of the field of human thought. The general philological movement was at first humanistic in that it turned aside from philosophical and rational systems, and attempted to restore past civilizations. It was a study of culture. Later, under the influence of natural sciences, of the historical method, of Darwinian theories of evolution, and of similar developments of modern thought, philology tended to take a broader aspect than that of humanistic study only. There were thus developed the psychological, social, and historical aspects of the modern science of philology. Modern philology may be most fitly regarded as beginning with Friedrich August Wolf (*q.v.*). The first modern to call himself a philologist, Wolf, described himself in the matriculation book of the University of Göttingen, under date of April 8, 1777, as *studiosus philologiae*. As student and later as teacher of philology, Wolf defines his subject compactly but broadly as the biography of a nation. The purpose of it was to reconstruct all the life of a past period which can be recovered from records. These records include of course not only language, but all other forms of recorded knowledge or experience. Wolf's other name for philology was *Alterthumswissenschaft*, the science of antiquity. But by antiquity Wolf means only Greek and Roman antiquity. The term is so limited for various reasons, *e.g.* because these peoples only have left abundant records of their life, because of the importance of the civilization of the Greeks and Romans for modern civilization, etc. But the general theory of philology, as the biography of a nation, does not imply a limitation to the Greek and Latin peoples, and if circumstances permitted, a Hebrew, an Egyptian, and other philologies would be possible. The aim of philology should always be, however, in Wolf's conception, the synthetic presentation of the whole life of a people at a definite period. Wolf was thus interested in language, literature, art, etc., in themselves only as each contributes its share to the unified picture of the life he was attempting to reconstruct. Philology thus becomes, in his mind, the recalling to life of historical Greek and Latin civilization, and it presents an organic conception of the subject lacking in classical and Renaissance scholarly investigation. In the carrying out of this scheme, Wolf makes the following divisions of the subject in his *Fundamentaltheile der Alterthumswissenschaft (Vorlesungen, Inhalt, p. v ff.)*:

(1) Grammar, or the study of language (merely, however, for the practical purpose of acquiring ability to read texts).

(2) Hermeneutics, "*Erklärungskunst*," defined as

the art of "comprehending the ideas of another just as he would have them comprehended." (*Vorlesungen*, I, 271.)

(3) Criticism, the rules by which we determine the age, the genuineness, or the authorship of works, the correctness or incorrectness of words, of passages, etc.

(4) The geography of antiquity.

(5) The political history of antiquity.

(6) *Antiquitates*, "Alterthümer," by which Wolf means allusions to ancient customs, beliefs, and practices.

(7) Mythology.

(8) Literature, sciences, and arts among the Greeks and Romans.

(9) History of Art, i.e. the study of the works of art of the ancients, including archaeology, numismatics, epigraphy, architecture, sculpture, and painting.

It will be seen at once that Wolf was a system builder, and so also were his immediate successors in the development of the theory of philological studies. August Boeckh, who lectured on the methodology of philology from 1809 to 1865, proceeded on the basis of Wolf's definitions. His is the broadest possible conception of philology: "die eigentliche Aufgabe der Philologie das Erkennen des vom menschlichen Geist Producierten, d. h., des Erkannten" (*Encyk.* p. 10), which translated reads, "the real task of Philology is the restoring to knowledge of that which has been matter of knowledge." The subject is again defined as "die Nachconstruction der Constructionen des menschlichen Geistes in ihrer Gesamtheit" (*Encyk.* p. 16), "the putting-together again in its entirety of all that the human spirit has fashioned". Wolf had made philology the reconstruction of the past culture and life of a nation, more specifically of the Greek and Roman nations. Boeckh extends the definition to include the reconstruction of the culture and life of all past existence, so far as that existence may be made known through the records it has left behind. Philology according to this conception comprises all history in the narrow sense of narrative, institutional and social history, all historical linguistics, literature, art, science, etc. It excludes philosophy in so far as philosophy is concerned with first causes, not with the content, meaning, and value of records of thought; it excludes also science in the sense that investigational science endeavors to determine the immediate and the actual, although when science becomes historical and concerns itself with man's activity and self-expression in the past, as, for example in the science of folklore, it falls within the limits of Boeckh's definition. The necessity of subdivision of the great subject is acknowledged by Boeckh, but the theoretical definition is defended on the ground that no science is completely realizable, e.g. the biologist theoretically sets himself the unattainable goal of knowing all about all animal life, and the chemist cannot exhaust all the possibilities of combination among natural elements. It may be pointed out that Boeckh adds to Wolf's conception of philology also in that he assigns

a higher place to linguistics, which he would study not only to gain a practical reading knowledge of language, but he would have languages considered in themselves as expressions of the life of the people who develop them.

The difficulties in the way of any practical realization of this general scheme of philology are in certain respects obvious. Any valid criticism of Wolf's theory would apply as well, but with more weight, to Boeckh's theory. Two main difficulties may be noted: (1) the student who would carry out Wolf's or Boeckh's scheme must possess combined qualities, i.e. the critical faculty for the gathering and preparation of his material, and second the constructive and artistic for its composition. The qualities of mind required by the first half of the task are memory, critical judgment, sense of order, "learning" in the specific sense. The qualities of mind required by the second half of the task are constructive imagination, a sense of the relative importance of parts, and the poetic faculty which gives life to an assemblage of facts. The two groups of characteristics are not necessarily mutually exclusive,—witness Jacob Grimm and Sir Walter Scott,—but actually they are not often found in combination. "As a rule, one has dwarfed the other; either the creative fancy, scorning a solid masonry of facts, builds its castles in Spain without carpenter and architect, or a hesitating exactness may become the fetish to which the children of the imagination are sacrificed" (Oertel, *Lectures*, p. 20). The second fundamental difficulty which obstructs the path of the philologist of Wolf or Boeckh's way of thinking is the vast extent of inherently heterogeneous subject matter which he must command and assimilate. The specialist is necessary for the preparation of the material, but the specialist is manifestly incapable of spreading himself over the whole field. The nearest approach to a realization of the synthetic idea is to be found in the *Grundriss* plan of collaboration, various scholars of supposedly the same general point of view taking each his special part in a harmoniously elaborated scheme of presentation. Thus Paul, *Grundriss* I, 1, joins himself to the school of Boeckh when he expresses the conviction that "die Einzelnen Gebiete in welche man das Kulturleben eines Volkes zu zerlegen pflegt, in der wissenschaftlichen Untersuchung nicht isoliert werden dürfen." And he also extends Boeckh's formula, "das Erkennen des Erkannten," in that he insists that the philologist must not only know again what was in the clear consciousness of individuals in past times, but also must be able to see into forces and streams of tendency which were not clearly perceived; he must see relations of cause and effect, and follow out lines of historical development. In practice Paul's *Grundriss* is the fullest attempt made to realize the

broad conception of a philology of the Germanic peoples. This work was planned and executed under the general supervision of Hermann Paul, assisted by special students, such as Sievers, Kluge, Noreen, Wright, Brandl, Luick, R. Kögel, and others. The work as it was finally executed consists of fifteen parts, not indeed arranged in any strictly systematic method so as to give a philosophically unified interpretation of Germanic civilization. The various parts are as follows: (1) the meaning and purpose of Germanic philology, a theoretical discussion and definition of the subject by Paul; (2) history of Germanic philology, also by Paul; (3) methods of Germanic philology by Paul; (4) history of Germanic alphabets and of writing by Sievers and Arndt; (5) *Sprachgeschichte*, the history of the various Germanic languages, by different scholars; (6) *Literaturgeschichte*, the history of the various Germanic literatures, each treated separately, as the languages are, by a specialist; (7) historical and theoretical discussion of Germanic meter, (8) ethnography (Bremer); (9) *Wirthschaft*, i.e. the practical arts of agriculture, etc.; (10) *Recht*, i.e. law and legal custom; (11) *Kriegswesen*, war and its traditions; (12) Mythology; (13) *Heldensage*, i.e. heroic traditions; (14) *Sitte*, i.e. social custom and formalities; (15) *Kunst*, (a) *bildende Kunst*, painting, architecture, and sculpture, (b) music.

Specialized Use.—Although the broad philosophic definition of philology as elaborated by the theorizers of the school of Wolf and Boeckh will be generally accepted by philological students as true to the underlying purpose and methods of their investigations, popularly the subject is more narrowly conceived as equivalent to linguistics. "Philology," says the *Encyclopedia Britannica*, "is the generally accepted comprehensive name for the study of the word; it designates that branch of knowledge which deals with human speech, and with all that speech discloses as to the nature and history of man." Two main definitions are given in the *New English Dictionary*: (1) "Love of learning and literature; the study of literature in a wide sense, including grammar, literary criticism and interpretation, the relation of literature and written records to history, etc.; literary or classical scholarship; polite learning. Now rare in general sense"; (2) a special sense, the usual one in modern use, "the study of the structure and development of language; the science of language; linguistics." The second sense is really one branch of the first, which represents in some respects the classical conception of philology, with additions from the broad synthetic definitions of the Wolfian school.

These narrow popular conceptions of philology are to some extent forced upon the serious student by the practical exigencies of subject matter. Obviously the Wolf-Boeckh theory,

though valuable as an ideal from which to draw inspiration, is not one to be applied in detailed practice. Perhaps the definition which most nearly describes the actual work of philologists might run as follows: Philology is the study of culture as it is recorded in language. This definition implies that language itself is an object of study for itself, since it is one of the expressions of the cultural development of the people that employ it. It implies also that the study of literature is a branch of philology when such study is concerned with the interpretation of the text of literary monuments, and with their history and value as illustrating civilization. If philology be defined as the restoration to knowledge of past thought through the medium of the word, it is apparent that no study of literature, however simple and however approximately contemporary the literary monuments may be, can be carried on without the employment in some degree of philological methods. The so-called philological approach to the study of literature has been at times not without its unwise advocates. To parse through the whole of *Paradise Lost* and to examine the etymology of every word may be philological study of a kind, but it can scarcely be called literary. Philology must serve as a handmaiden to literature in the interpretation and elucidation of texts, but there is no immediate way of entry into the processes of literature through the study of individual words. Among other practical uses of philology regarded as linguistics may be mentioned that of seeing that the historical records of the speech and literature preserved in manuscripts and in texts, often few in number and difficult of access, are brought to light and secured against the accidents of time by publication. The reëditing of texts in the light of fuller modern scholarship is also a duty of the philologists not to be evaded. Sound philological principles are manifestly as important in the editing of a modern text as of one of medieval or ancient times. Philology may also be of service in the daily practical use of language, especially in determining questions of propriety and conduct in language. (See article on *ENGLISH USAGE*.) A still larger field of practical philology is to be found in the whole province of rhetoric. Rhetoric attempts to teach an art of language, and instruction in this art is greatly assisted by the ability of the teacher and student to analyze and to comprehend the principles of the art. Rhetoric consequently, if it means anything at all as a systematic discipline, means the application of the methods of observation and analysis to the processes of language expression upon which the science of philology rests. Other practical applications of philological science, e.g. the production of descriptive grammar for the use of the students of a language who are seeking to acquire a practical control over it,

the analysis of speech sounds as an aid in the teaching of spoken language, etc., are too obvious to require mention.

The present academic status of the study of philology has been implicitly indicated in part in the description which has been given of the subject. A more detailed account of the courses will be found in the articles on MODERN LANGUAGES AND LITERATURE; also in those on GREEK LANGUAGES AND LITERATURE; LATIN LANGUAGES AND LITERATURE; SEMITIC LANGUAGES AND LITERATURE. G. P. K.

PHILOSOPHICAL SYMBOLISM.—See SYMBOLISM IN EDUCATION.

PHILOSOPHY.—Definition and Scope.

The term philosophy (in the form of the verb *φιλοσοφῶν*) seems first to have been used by Herodotus and Thucydides in its literal sense, to denote the desire or pursuit of wisdom. The speculative bias of the Greeks made them restrict the term philosophy to theoretic knowledge only, i.e. knowledge pursued for its own sake as opposed to that which is technical or immediately practical. The terms science, true knowledge, and philosophy are used almost interchangeably by Plato and Aristotle. The idea that philosophy is not ordinary knowledge but has for its object something of superior worth, to wit, the real as opposed to the phenomenal, is due to the Platonic doctrine that true knowledge can be only of the immutable and the eternal (*Rep.*, 480). Aris-

totle also emphasizes the fact that philosophic or scientific knowledge is reasoned or demonstrative, and, therefore, depends on knowledge of causes or principles. Though Aristotle wrote on political and natural history he seems to have clearly distinguished between history and science or philosophy. Both Plato and Aristotle, while setting a high value on mathematics, hesitated to apply the term philosophy to it. Thus Plato put mathematics in the borderland between true science and opinion; and Aristotle, while explicit in his statements that metaphysics, physics, and mathematics are the three parts of theoretic philosophy, and in his reference to metaphysics as the first and to physics as the second philosophy, does not explicitly refer to mathematics as the third philosophy. Nevertheless, mathematics did not become generally dissociated from philosophy until the Alexandrine period (e.g. Euclid), and even later we find the book of Sextus Empiricus, *Adversus Math.*, directed against the philosophers or metaphysicians.

The distinction between philosophy and the special sciences seems to have been accentuated by the Stoic and the Epicurean philosophies, with their emphasis on ethics as the major portion of philosophy. In the light of the popular use of the term philosopher as synonymous with that of moral teacher or guide, and the prevailing idea of philosophy as a mode of life, pursuits like those of Archimedes could not be referred to as philosophical. At any rate, the Alexandrine period finds a number of special sciences cultivated separately from philosophy.

In mediæval times, philosophy seems to have been used to denote all the knowledge which can be acquired by natural reason without the aid of revelation. In practice, this meant all the subjects treated by "the Philosopher," i.e. Aristotle; and as these formed the substance of all arts courses, the faculty of arts became known as the faculty of philosophy. The "three philosophies" denoted moral, natural, and metaphysical philosophy.

As a result of the development of natural philosophy into the independent science of physics, and the emphasis on the problems of thought or consciousness in writers like Locke, the term metaphysics gave way to the term mental science or intellectual philosophy. As a result, also, of the expansion of modern science and its imperative demand for specialization, the parts of moral philosophy known as jurisprudence, law of nature, politics, and economics, — subjects on which an eighteenth century professor of philosophy like Adam Smith was expected to lecture, — soon became objects of study on the part of specialists who did not concern themselves with the rest of philosophy. For the last forty years empirical psychology has been assuming more and more the rôle of a special science, as independent of philosophy as the science of optics. In our

own day there is a strong tendency for investigators in the field of logic to regard their subject as a branch of either psychology or mathematics; and an increasing number now view the field of ethics as part of sociology or anthropology.

After the special sciences have thus been carved out of it, what, if anything, is left of philosophy itself? The typical answers to this question may be arranged in three groups, between which hard and fast lines cannot be drawn:—

(A) Those that deny that there is any peculiar subject matter or method in philosophy. This is the view of the agnostic and positivist schools. To both Spencer and Comte philosophy consists simply in the unification or coordination of the various sciences. In Spencer this unity is a mere juxtaposition,—the only bond uniting the various sciences being the fact that they all have certain vague general laws of evolution in common. In Comte the unity is one of end. In constituting the positive philosophy the various sciences are subordinated to each other in accordance with the needs of the positive polity. In harmony with the above is the popular view, supported in some respects by Paulsen, that philosophy is simply the sum of the general portions of the different sciences.

(B) Those that insist that philosophy still has a subject matter distinct from that of the special sciences, viz. the real or the rational. This group includes representatives of most diverse schools of philosophic thought, who, of course, conceive this subject matter in different ways. Thus, the Hegelian school conceives the subject matter of all philosophy to be the ultimately real, or absolute Idea, a knowledge of which we obtain by a system of reasoning. The mystic schools all conceive the real, which is the quest of philosophy, to be in the ineffable One attained in certain experiences, called feeling or intuition. Between these two schools may be placed an influential group of thinkers like Münsterberg, Duhem, and Bergson, having little in common save the view that the special sciences all deal, not with reality, but with systems of useful constructions of the mind, and that it is, therefore, left to philosophy to deal with reality itself, by intuition (Bergson), by dialectic reasoning (Münsterberg), or by faith and reason (Duhem).

(C) Mediating between (A) and (B) is the view that philosophy has a distinct subject matter of its own, but that this subject matter is no other than the system of the special sciences; that is, that philosophy is itself a special science, viz. the science of the sciences. This science may be conceived in quite naturalistic fashion. . . . "Sciences, then, are as real things as facts themselves. . . . We can analyze them as we analyze facts, investigate their elements, composition, order, and sub-

ject" (Taine). The view, however, which has, owing to the influence of Herbart, Wundt, and the Neo-Kantians, prevailed for the last generation has been a more critical one. It is supposed to be the business of philosophy to analyze and criticize the fundamental concepts and assumptions of the special sciences, and to build up a *consistent* world view on the basis of this critical work.

The greater intimacy, however, between philosophy and the special sciences during the past decade has brought to light the following considerations: (1) that the criticism of the assumptions of the various sciences can be made only by those who are already in possession of a certain definite *Weltanschauung*, (2) that there are no contradictions infesting the special sciences to such an extent that the scientists are helpless and need the aid of philosophers, and (3) that the fundamental concepts of the different sciences can be analyzed only in the light of the special content of these sciences, and that the specialist is, if he undertakes it, the best qualified to make this analysis.

The feeling has also arisen recently that the function of philosophy is obscured by a too close assimilation of it to science, and that its nature is in many respects akin to art and poetry (see *Journal of Philosophy*, vol. 7, p. 406).

In spite, however, of all these diverse views as to the nature of philosophy, all are substantially agreed that its aim is to give us a coherent view, or outline chart, of the universe and the place in it of man, the external world, and the higher Reality, if there be any. There is also a practical agreement that a department of philosophy in a college or university should teach metaphysics (including philosophy of mind, and philosophy of religion), logic, ethics, aesthetics, and the history of philosophy. Professor Fullerton has made the interesting attempt to show that these apparently diverse disciplines (including psychology) have not been grouped together by mere accident, but that they all have something fundamental in common, viz. that they all raise problems of reflective thought, i.e. problems involving the critical examination of the meaning of our ideas. (*Intro. to Phil.*, pp. 223–260.)

Metaphysics, logic, ethics, and the history of philosophy, then, represent the irreducible minimum of a department of philosophy. Though many philosophers emphasize the primacy of psychology as a philosophical discipline, psychologists as a rule are anxious to have their science free from all philosophic entanglements. In many of our universities psychology now forms an independent department, and at the St. Louis Congress of Arts and Sciences (1904) the psychologists were grouped not with the philosophers but with the other students of natural science. In France lectures on sociology are still given by

professors of philosophy and this is also true of other Latin countries, especially Spanish America where French positivism has been very influential. No one, however, doubts that the specialization of the social sciences is inevitable. In the United States courses in education are often given by the department of philosophy, but though philosophy must always play a prominent part in educational theory, it is only for administrative reasons that the two departments are united. In many American colleges courses in the history of mathematics, chemistry, etc., are given by the departments concerned; but in the very few instances where courses in the general history of science are given, this is done by the department of philosophy. In European institutions even the history of special sciences is given by the department of philosophy; and when a physicist like Mach begins to lecture of the history of his own science, it is thought proper to transfer him to the department of philosophy. The history of science is, however, a very much neglected field in any case. For the individual philosophic disciplines, see *ÆSTHETICS*, *ETHICS*, *LOGIC*, and *METAPHYSICS*. For schools of philosophic thought, see *MATERIALISM*, *SPIRITUALISM*, *IDEALISM*, *REALISM*, *PHENOMENALISM*, *RATIONALISM*, *MYSTICISM*, *EMPIRICISM*, *SCPTICISM*, *CRITICISM*, *POSITIVISM*, *INTELLECTUALISM*, *VOLUNTARISM*, *PRAGMATISM*, *MONISM*, and *PLURALISM*.

History of the Teaching of Philosophy. —

Among the Ancients. — India and China seem to be the only Oriental countries that independently developed definite schools of philosophy, i.e. bodies of doctrine more or less systematically and continuously taught from generation to generation. Thus we have in China the speculative school of Lao-tze, Licius (Lieh-tzi) and Tschauing-tze, and the moralistic school of Confucius and Mencius beginning in the sixth century B.C. and continued into the Christian era. In India we have six great historical schools of which the Sankhya, Vedanta, and Yoga are best known in the West.

The earliest form of teaching took place under the form of voluntary discipleship; the disciple attended the master and learned from him in the course of ordinary conversation or whenever the spirit moved the master. Such a life frequently involved celibacy. The typical Hindu teachers of philosophy live apart on a mountain or in a grove in simple abstemious fashion, spending the time "in listening to serious discourse and imparting their knowledge to such as will listen to them" (Max Müller, *Six Systems of Indian Philosophy*, p. 35). We also hear of philosophic and religious congresses and of philosophic disputations at kings' courts, and, in Buddhist times, of monasteries, famous schools, public lectures, etc.

Before the extensive use of textbooks was possible, instruction was given in the form of short mnemonic aphorisms, easy to hand on unaltered from generation to generation, but so brief and packed with meaning as to need extensive commentary to make them intelligible. Such teaching, therefore, tended to become dogmatic and esoteric.

The Greco-Roman Period. — The earliest form of philosophic teaching among the Greeks was probably also in the form of aphorisms of Wise Men; and Thales, the founder of the Milesian school of philosophy, was regarded as one of the Seven Wise Men of Greece. Popular philosophic instruction was also given by the wandering bards, of whom Xenophanes, the founder of the Eleatic School, was a remarkable example. The Pythagorean School was definitely organized, and demanded certain modes of life of its members to enable them to pursue its characteristic studies.

The expansion of Greek life and culture in the fifth century B.C. brought into existence the professional teacher or sophist. The wandering sophist was an itinerant university, gathering all sorts of pupils and teaching them all subjects. The various schools which owe their impulse to Socrates were largely influenced in their foundation by their feeling of protest against the introduction of professionalism into the life of culture. Socrates taught by means of his peculiar method of questioning — noteworthy in the history of education as an indication of the complete absence of the authoritative note, and thus characteristic of the spirit of free inquiry among the Greeks. Plato tried hard to avoid the lecture system of the sophists, but Aristotle returned to it. Socrates refused to accept any fees, and Plato was too independent, but Speusippus, Plato's successor in the Academy, found it necessary to accept fees. At the end of the fourth century B.C. we find separate and distinct from the schools of rhetoric four well-established permanent schools of philosophy (the Academic, the Peripatetic, the Stoic, and the Epicurean) which made Athens the world's center for philosophic instruction. These schools continued their existence till closed by Justinian (in 529). The corporate character of these schools (for which see *ATHENS*, *UNIVERSITY OF*; *GREECE*, *EDUCATION IN*; *UNIVERSITIES*, etc.) made them emphasize adherence to traditional doctrine of the school rather than independence of thought.

With the introduction of Greek culture into Roman society, philosophy became a standard form of education coordinate with jurisprudence, rhetoric, and medicine. It became customary for the great families to send their sons to Athens to study philosophy. Philosophic education at Rome, however, was mainly carried on through private tutors who regarded their office as that of a physician to the morals of those whom they instructed.

Disinterested play of the intellect gave way, under this régime, to the inculcation of sound moral maxims or precepts (Seneca, *Ep.*, 49, §5). We have, however, pictures of lecture theaters crowded to hear philosophic orations or debates between rhetorical philosophers. We also hear of philosophic missionaries, like Apolonius of Tyana, exhorting and appealing to the crowds in the market place.

Alexandrian Schools and Arabic Influence. — In the third century B.C. the great libraries and museums and the liberal policy of the Ptolemies towards scholars made Alexandria (see ALEXANDRIA, SCHOOL OF) an endowed research university, a great center of learning rather than of instruction. It became also the chief meeting place of Greek philosophy and Oriental religion. From it issued Philo's doctrine of the Logos (see PHILO OF JUDEA), and the chief intellectual moulds for the dogmas of the Christian Church. In the revival of religious and speculative philosophy in the third century (A.D.) Alexandria was also the birthplace of Neo-Platonism (*q.v.*), which, by claiming to unite and restore the philosophy of Plato and Aristotle, became the rallying ground for those who wanted to maintain the old Hellenistic culture against the rising tide of Christianity. It was also principally at Alexandria that Christianity, under the leadership of men like Clement and Origen (*qq.v.*), began to yoke Greek philosophy into its service. The catechetical schools (*q.v.*) of Egypt and Syria were the first to introduce the study of philosophy into Christian schools. From the Syrian schools of Edessa and Nisibis the study of philosophy was carried into Arabic or Saracen culture. The Arabic translations of Aristotle were carried across North Africa into the Moorish centers of learning in Spain, and there they were, together with Arabic commentaries, translated into Latin and brought back to Europe, principally through Hebrew translators.

The Middle Ages. — In the fifth century, with the barbarian invasions and the decay of Roman culture, philosophic study became practically extinct in Western Europe. Some logic, however, continued to be taught as a part of the cycle of liberal studies; and when the Christian monastic schools took over the elements of the later Græco-Roman system of education, logic remained the only school discipline having any connection with philosophy. (See article on LOGIC.)

Though Porphyry's *Introduction* stated the problem of universals out of which medieval philosophy grew, the regular school teaching of logic was mainly formal. While there were noted examples of philosophic speculation, as John Scot in the ninth and Gerbert in the tenth century, it was not until the end of the eleventh century that philosophic teaching may be said to have been resumed in what had been the Western Empire.

The revival of philosophic study received its

impetus first from the theologic interest in the question of universals, secondly from the recovery of the more important Aristotelian logical writings (the *Analytics*, etc.) either in Boethius' translation or that of Jacob Clericus (1128), and thirdly from the introduction of Aristotle's *Metaphysics*, *Physics*, and *Ethics*, through the Arabic translations and commentaries, at the end of the twelfth century. After 1254 logic and philosophy formed nearly the whole of the curriculum, the old quadrivium being relatively neglected. No uniform or sharp line was at first drawn between the universities and the older monastic schools. The latter continued to teach logic and sometimes one or other of the "three philosophies." As late as 1540 we find Ferrerius publicly lecturing in the chapter house of the Abbey at Kinloss on Aristotle's *Ethics*, *Politics*, *Physics*, *Metaphysics*, *Economics*, and *Psychology*. The growth of the universities, however, led the grammar, burgh, and landschulen to restrict themselves to grammar and logic and sometimes to the former only. (See UNIVERSITIES and MIDDLE AGES, EDUCATION IN.)

The logic of the syllogism, however, extended its sway over the whole range of higher education. Every study was reduced to a number of "questions" and thus made suitable for syllogistic reasoning. The presence of a large body of authoritative doctrines in the form of unquestioned self-evident principles, sentences from the Bible, the Christian Fathers, the "Philosopher," and the Doctors of the Church, made this procedure possible. Syllogistic disputation also adapted itself to the strong controversial spirit of the medieval age. The disputes between the nominalists and the realists were carried on with such violence that the king of France had to forbid all disputations on such "inflammatory subjects." In an age devoid of our modern means of publication and dissemination of the news of the intellectual life, the wandering scholar provided a means for intellectual entertainment and popular instruction.

The Renaissance and Later. — The movement known as the Renaissance brought back to Europe Greek philosophy other than Aristotle; and even Aristotle began to receive a new interpretation in the light of the Greek text and the commentaries of Alexander Aphrodisias instead of the commentaries of Averroës. The spirit of free inquiry led to a questioning of the classic medieval view of the universe based on Aristotle, and brought Plato and Plotinus (*q.v.*) to the fore. University teaching of philosophy, however, was not profoundly affected by this movement, which was organized in societies or academies like the Florentine and supported by liberal princes. The humanists approached philosophy from the literary rather than from the logical or "scientific" side. The universities substituted the Greek text of Aristotle for the Latin

one, and some of Plato's dialogues were admitted into the orthodox curriculum, but the old methods remained. Logical disputations and the public defense of these continued to be required for graduation, even in the medical faculty, down to the nineteenth century.

Outside of the universities, also, began the mathematical-physical philosophy of Copernicus, Keppler, Descartes, Galileo, and Leibnitz. This new philosophy found its support in the great scientific academies (*q.v.*) founded in the seventeenth century. To a certain extent this new philosophy also found support from the new liberal culture which began in France under Louis XIV and which was supported by all the liberal courts of Europe. Leibnitz, who disdained to seek a university position, is the typical representative of this new culture and philosophy. Cambridge seems to have been the first university to hear the appeal of men like Barrow to stop speculating about "*entia rationis, materia prima*, and such like scholastic chimeras" and turn (1659) to the mathematical philosophy of Galileo and Descartes. But even here the influence of its own Newton was comparatively slight throughout the eighteenth century. In Germany the scholastic philosophy was replaced, after a struggle in which the authority of the liberal Frederick the Great proved the decisive factor, by the Leibnitz-Wolffian philosophy of "reasonable thoughts." Through the influence of men like Martin Knutzen and his more famous pupil, Kant, the Newtonian view of the physical universe entered into the universities. In France the removal of Church control over the faculty of philosophy in the eighteenth century made possible the introduction of Descartes. The modern scientific, as opposed to the scholastic spirit did not, however, completely triumph in academic philosophy until the second half of the nineteenth century.

Of great importance to the teaching of philosophy was the change of the language of instruction from Latin to the vernacular. This change was begun, in spite of bitter opposition, by Thomasius at Halle, in 1694, and was not completed until the first quarter of the nineteenth century. The poverty of material in the old scholastic philosophy was hidden by the learned language in which it was delivered. When men began to lecture in the vernacular they had to attend more to the substance of their teaching.

Philosophy in the American College. — *History.* — From the beginning, philosophy was taught by the class tutor on the basis of the scholastic manuals then used in England. Before 1664, when the three-year curriculum prevailed at Harvard, provision was made for logic and physics in the first year, ethics and politics in the second, and philosophic disputations in the third. At the end of the seventeenth century we find logic taught in the first two years from the Latin manuals

of Peter Ramus and Burgerdicius, in the third year Henry More's *Ethics* and Dr. Morton's *Physics and Metaphysics*, and in the fourth year Divinity. At the beginning of the eighteenth century Locke's *Essay on the Human Understanding* was introduced into the curriculum, and remained throughout the eighteenth century the starting point of American philosophy, as can be seen in such different types as Franklin and Jonathan Edwards. Berkeley and Hume had relatively little influence, the former being a Bishop of the Church of England and the latter suspected of being both a sceptic and a tory. The deistic controversy and the question of free will in relation to Calvinistic theology limited almost entirely the range of philosophic interest. At the end of the eighteenth century new influences began to come in, French materialism as represented by Priestley, and Scotch realism as brought over by President Witherspoon. The former was influential mainly in the South, but the latter swept the country, and in the middle of the nineteenth century was the predominant influence in the philosophy taught in American colleges. Reid, Stewart, and Brown were several times reprinted in America, and in the second third of the nineteenth century Hamilton's lectures went through several American editions and abridgments. Paley's *Moral and Political Philosophy* and his *Evidences of Christianity* also came in at the beginning of the nineteenth century. In the fourth decade of the nineteenth century Cousin and French Eclecticism became influential. Partly through the influence of German immigrants and the St. Louis School of Philosophy, headed by Dr. William T. Harris, and partly through the influence of teachers trained in Germany, Kant and Hegel began to dominate academic philosophy in the last quarter of the nineteenth century. Though Mill and Spencer were widely read, they had little influence on the academic teaching of philosophy.

By the beginning of the nineteenth century separate chairs in mathematical and physical science were established in most American colleges, but so late as 1838 the course in philosophy at Amherst included mechanics, electricity, etc. In the first half of the nineteenth century economics was separated from philosophy in some of the larger colleges, but this separation was not completed in other colleges before the twentieth century. The modern period of the American college with its large field of electives may be said to have begun in the last quarter of the nineteenth century. Previous to that, philosophy was all prescribed and generally crowded into the last year or two, as one of the higher branches calculated not only to train the student in scholarship but to fit him for practical life.

Aim. — It is agreed by all that the training of specialists in philosophy is beyond the scope

of the American college. Is philosophic training, then, an indispensable element of a liberal education for citizenship in the larger life? In urging an affirmative answer the following points have been made:—

(1) Philosophic knowledge is a desirable end in itself. "Just to face these profound problems concerning the being, the origin of, and the destiny of man . . . just to know that there are such problems, and something of how the soul of man has in thought and feeling responded to them, is of itself no small part of liberal culture." (Ladd, *Educational Review*, X, p. 232.) Even if we regard philosophy as setting or solving no problem, the inspiration which comes from the knowledge of man's search for the thoughts that give value and dignity to human life is one of the best things that a liberal education can offer.

(2) Others emphasize not so much the knowledge itself as the philosophic habit. The philosophic or reflective habit is absolutely essential in order to enable the student to bring together the diverse fragments of knowledge picked up in the different departments, and to organize the contents of his mind into some unity. The need for such unity is especially evident when one reflects on the chasm which generally separates the religious ideas which the student brings to college from the scientific ideas which he gathers in such courses as geology, biology, or psychophysics. The philosophic habit prevents a man from becoming a narrow partisan, and in this way it is one of the finest flowers of culture.

This last aspect of the situation leads some to emphasize the ethical aim in philosophic teaching. More important than a knowledge of philosophic problems past or present is it that the student should be started in the business of philosophizing for himself. Students as a rule come to college slaves of traditional forms of thought and conduct, and to train them to become freemen of the intellectual life is the function of the devoted teacher of philosophy. Just because its results are not so certain as those of mathematics or the natural sciences, the student cannot find the answer before thinking the matter out for himself. Most people doubtless get this training in actual life in the school of experience; but philosophic training accomplishes it at less expense.

Methods.—No other teachers have, as a body, given so little attention to the pedagogy of their subject as the American teachers of philosophy; with the result that at least one professor of philosophy confesses, "It is possible that there has been more poor pedagogics in this field throughout the ages than in any other branch of the university" (*Journal of Phil.*, VII, p. 569). The pedagogic principle which has revolutionized modern science teaching, viz. to begin with the concrete

nearest the pupil's own experience rather than with the abstract elements of the subject, has not yet found full recognition in philosophic teaching, though some philosophic teachers have exemplified it beautifully. The philosopher is peculiarly apt to think that he is going from the simple to the complex when he is really proceeding from the abstract to the concrete (*q.v.*), forgetting that the abstract elements familiar to himself are strange and difficult of apprehension to the beginner.

The peculiar difficulty about philosophic teaching is that it involves on the part of the pupil an apparently different mode of thinking from the one to which he has been accustomed, a peculiar turning back on one's usual ideas; and this undoubtedly appears to the beginner both forbidding and fruitless. The problem, then, is how to make philosophic problems real to the student. How is the student to be seriously interested in philosophic issues and to be trained in the difficult art of philosophic thinking? We must show the vital importance of the subject from the beginning. For unless we succeed in showing the student that philosophy is a matter of life and death, essential to his own intellectual salvation, we cannot generally draw out the best efforts.

The pedagogic means generally used in the teaching of philosophy are the lecture, the quiz, the assigned reading, the essay, the recitation, discussion, and the pamphlet or question syllabus. As a method of philosophic teaching the lecture has, besides the disadvantages incident to it in other subjects, the added one that it must, in order to enable the student to follow it intelligently, necessarily avoid intricate questions or very close reasoning. The philosophic lecturer may have to present examples of reasoning as closely knit as that of the mathematician, but he has not the advantage of making it all visible on the blackboard. To offset this partly, some teachers put an outline syllabus in the hands of the pupils before the lecture. Even so, the lecture seems well adapted only to introduce or open up a topic and to summarize a discussion.

In many of our large colleges the professor gives two lectures a week, and an assistant meets the class, usually in smaller sections, for quizzes on required reading or on the substance of the lectures. The attitude of the students who, judging by the position of the assistant, regard the quiz as of secondary importance, makes this arrangement a more or less perfunctory affair, seldom productive of genuine enthusiasm. It is generally felt that the quiz should give way to the full recitation where the student and instructor can discuss the subject matter at length and not be compelled to take up any new topic before coming to a satisfactory termination of the one in hand.

The objections to discussion, especially

when instructors allow students to discuss with each other in class, are: (1) It is apt to give students the impression that philosophy is all a matter of opinion. (2) The variety of views that come into discussion is apt to be confusing to the beginner. (3) The discussion is apt to run into very minor matters and make students lose sight of the big issues. Discussion frequently degenerates into repetition of opinions, with no advantage except, at best, developing the student's cleverness at finding arguments. (4) Discussion or Socratic questionings must be profitless if students have not some previous knowledge of the subject to be discussed, and have "no method of ordering their thoughts in truth-giving directions."

In answer to these it may be maintained (1) that philosophy must begin with opinions, but opinions have to be made systematic and consistent with the whole of experience. The age of dogmatic manuals of absolutely certain truths is past, and those who sigh for them, as after the fleshpots of Egypt, do so in vain. (2) A critical attitude to one's opinion is the most effective method of philosophizing. (3) The teacher can correct the shortcomings by actively and critically guiding the discussion without dogmatically asserting his own opinion more than is necessary for effective summaries or searching questions. (4) Discussion has been called by Professor James the philosopher's laboratory, and the mere clash of one's opinion with that of others is an illuminating experience preventing one from returning to previous narrow dogmatism. It must also be maintained that philosophy does not have to start with a clean slate and that it may and must, to be effective, grow out of what the student already knows and thinks.

A device which Professor Garman introduced, and which he considered as much of an invention as printing by movable type, is the pamphlet. In these pamphlets some problem is stated or developed, but without any definite solution. These are loaned to the student, who, thus shut off from the possibility of turning to the next page to find the solution, is compelled before entering the discussion in the classroom to think the matter over and formulate his own answer. The instructor is then in a position to know whether the students are taking serious hold of the subject.

The intensive reading of classical texts forms part of most courses in philosophy. The frequent writing of essays is now recognized as a powerful instrument to bring the student's ideas together and make them clear to himself. For this reason some teachers encourage their students to write on subjects on which the latter have little information, or on topics which have not yet been discussed in the classroom. The essay is thus a means to compel the student to think on the subject. The

reading of texts, however, needs elucidation, and both text and essay need to be supplemented by thorough discussion and criticism to make them effective.

Philosophic clubs in many of our colleges frequently increase interest in philosophic studies. In many of our colleges connected with graduate schools senior students also have the privilege of entering the seminar courses.

Organization of a Department of Philosophy.

— Philosophy is usually regarded as a difficult subject requiring some maturity and knowledge of other studies. Hence, it is considered advisable to begin the study of philosophy in the upper classes. This arrangement, however, limits the number of courses that the undergraduate can take, and teachers who are anxious that students should have the advantage of the more advanced courses are in favor of opening the philosophy department to sophomores or even to freshmen.

As so much depends on the starting point in philosophy, the question, "Which course should be given first," is of great importance. There is, however, nothing like agreement in the answer. The historical answer, of course, is logic, which has for over 2000 years served as a propædæutic to philosophy. Even the driest treatise on formal logic raises a number of distinctly philosophical issues. Thus the relation of the universal to the individual, of terms to objects, judgment to reality, etc., all lead to philosophic issues of deepest moment. But the dry and apparently fruitless character of syllogistic exercise seems to postpone rather than introduce the vital issues of philosophy.

A great many colleges now offer psychology as the first course. The plausible argument is made that acquaintance with the workings of the human mind is a prerequisite for philosophy. But the growing disfavor of analytic or non-laboratory psychology raises difficulties in the way of this mode of introduction to philosophy, and raises the doubt whether physiology or physics is not just as much a prerequisite for philosophy as psychology. At any rate, neither logic nor psychology contain enough philosophy.

The main issue seems to be, however, between those who believe in beginning with the history of philosophy and those who believe in beginning with some survey of philosophic problems. The great arguments for the historical introduction are: (1) that an approach through a survey of problems is apt to be partial and one-sided, and (2) that the history of philosophy gives one the proper perspective to appreciate the problems. In answer, however, it may be urged (1) that there is nothing pedagogically wrong in starting with a partial and one-sided view, provided we supply the motive power to enable the student to go on to a wider view. As a matter of fact the great historical system grew out of certain

problems. (2) The student cannot get the proper perspective of the history of philosophy without some preliminary appreciation of the problems themselves. The student is too immature to grasp the problems confronting Plato, Aristotle, or Descartes without having done any philosophic thinking on his own account. The effort on the part of teachers to simplify the teachings of the great masters and to make them intelligible to beginners leads to a certain conventionalization of their teaching, amounting to caricature. (See Owen Wister's *Philosophy Four*.)

Among those who urge that we should begin with the study of problems, no general agreement as to the content of these problems exists. Where such courses are given, they generally consist in an excessive simplification of the main problems of metaphysics and epistemology, i.e. an elementary treatment of the issues between monism and pluralism, idealism and realism, etc. As an introduction to the technical problems and to show how these problems grow out of real life, the fields of Religion, Science, Literature, History of Civilization, or Ethical and Political Problems have been suggested as supplying the proper material.

Metaphysics or General Philosophy.—The course in metaphysics in the seventeenth and eighteenth centuries was predominantly one in natural theology, with special reference, in the eighteenth century, to the deistic controversy. The introduction of Locke in the beginning, and of the Scottish philosophy at the end of the eighteenth century, brought psychologic elements into the course and soon led to separate courses in theism and mental or intellectual philosophy. The introduction of German philosophy in the latter part of the nineteenth century brought epistemologic considerations forward, and for a time it seemed as if epistemology would replace metaphysics. This tendency, however, to regard epistemology as independent of metaphysics is now on the wane, but separate courses in epistemology, the theory of knowledge, or philosophy of mind are still given frequently, for epistemologic questions are decidedly in the foreground of current philosophic discussion. In determining the scope and the setting of the problems in the modern course of metaphysics, Lotze's *Metaphysics* has been very influential. Recently Taylor's *Elements of Metaphysics* has become popular with American teachers.

Within the past decade there has been a revival of interest in classical metaphysics, i.e. in problems of ontology and cosmology, and courses on the philosophy of nature are increasing. It is urged on behalf of the latter course that its subject matter is concrete and that the student has a feeling of dealing with the actual world. The course in the philosophy of evolution given in several colleges belongs to the same category.

A course which has now almost disappeared

from the curriculum of the American college is the one in the philosophy of history. Under the influence of books like Bunsen's *God in History* and Hegel's *Philosophy of History* this course was frequently given. With the reaction against *a priori* methods in history this course fell into bad repute. Recently, however, several have urged its reintroduction in a form consonant with the spirit of present-day philosophy. Professor Hudson has advocated making it the introductory course in philosophy. (*Journal of Phil.*, Vol. VII, p. 426.)

History of Philosophy.—The course in the history of philosophy is like the study of history itself, a comparatively modern addition to the curriculum of the American college. The history of philosophy acquired the dignity of an academic discipline when Hegel made it appear as a rational system. At any rate, Schwogler's *History of Philosophy* (in Seeley's or Stirling's translation) seems to have been the first widely used textbook in this field in American colleges. One or two terms are usually devoted to this course. When the latter is the case, ancient philosophy is taken up in the first and modern philosophy in the second term. Little attention is given to medieval philosophy, and modern philosophy is usually ended with Hegel or Lotze, if not with Kant. In one or two of the colleges connected with graduate schools students have the opportunity of taking the special course in contemporary philosophy.

Courses in special periods of modern philosophy such as Continental Rationalism (Descartes, Spinoza, and Leibnitz) or British Empiricism (Locke, Berkeley, and Hume), are given in most colleges having a developed department of philosophy. Sometimes we have also special courses in Plato, Aristotle, or Kant. But almost no courses are given in the history of special fields such as logic, epistemology, or ethics.

With the waning of the metaphysical interest in the latter part of the nineteenth century, the history of philosophy threatened to absorb all the vitality of the philosophy department, and in the United States as in Germany the number of courses in the history of philosophy was almost equal to the combined number of all the other philosophic courses; but this historical wave is now receding.

In the teaching of the history of philosophy some emphasize the history and others the philosophy. The former method has been the hitherto prevailing one, — so much so that a recent college textbook in this field includes and emphasizes a great deal of geographic information. The generally recognized danger in the teaching of the history of philosophy is the breeding of a shallow skepticism through the kaleidoscopic picture of the rise and fall of different systems. To offset this, many teachers try to emphasize the historical continuity of philosophic problems. The at-

tempt, however, to minimize philosophic differences or the controversial element tends to exaggerate the conventionalization of the doctrines of the great philosophers. To guard against this, some reading in the sources, Plato, Descartes, Locke, etc., is frequently prescribed, even in the general course on the history of philosophy. To make this reading effective, however, intensive study is needed, and one has to give up the continuity of the historical survey.

Those who would emphasize the philosophy rather than the history in this course are quite willing to leave a great many lacunæ in the history and to select only those problems "which bear a significant relation to the issues and interests of our own time. In expounding a philosopher we should not try unsuccessfully to take the view point of his contemporaries, but should treat his problems and theories frankly from the standpoint of the present."

For the course in *Æsthetics* or *Philosophy of Art*, see article *ÆSTHETICS*.

Relation of Philosophy to the Other Departments.—The growing specialization in the different fields of human knowledge and in departmental teaching has brought about a strong habit on the part of teachers of philosophy to avoid all issues of fact which are the subject matter of the various sciences. This has tended to eviscerate philosophic teaching and to give it the appearance of a fruitless occupation with empty forms devoid of content. Fortunately, however, the sciences, especially physics and biology, are now outgrowing their juvenile fear of metaphysics, and the philosophic spirit is growing in the various sciences, as well as in the philologic and literary courses. Teachers of philosophy now advise their students to take various courses in other departments in order to make their philosophic study more thorough.

Philosophy in the Universities.—*The American Graduate School.*—The aim of graduate instruction in philosophy is to give the student the technical equipment needed to teach and to advance philosophic knowledge. It terminates with the conferring of the Doctorate of Philosophy. As the requisite philosophic ability is not widely distributed, our best graduate schools make it distinctly understood that this degree will be granted only to those who have distinctive ability in this field.

Graduate students in philosophy are (1) those who intend to teach philosophy, (2) students of divinity, or (3) students of other subjects, such as education, who regard advanced philosophic studies as helpful in the preparation for their special careers. Of these three classes only the first and part of the second try to complete the work necessary for the doctorate in philosophy; the others are usually satisfied with the M.A. in this branch of study, or, where the group system prevails, they choose it as one of their minors for the Ph.D.

Instruction is given mainly through lectures and seminar or research courses. The lecture in the graduate schools can be more frankly the statement of the lecturer's own philosophic views or interpretation of classical doctrines than is possible in the college. The distinctive work of the graduate school, however, consists in the training for research, and this is done principally in seminar courses. The essence of the seminar course is that the student should have the opportunity to report from time to time the result of some research, or his own constructive thinking, and have it subjected to the thorough criticism of his fellow students and of his instructor. Many courses not announced as seminars are practically conducted in this way (practica). The typical seminar is announced as restricted to some one general field, e.g. advanced logic, and the different members report on different topics in this field which they have chosen for the year. Some professors assign only one topic, e.g. the relation of mind and body, as the subject for the year, and various students report either on different aspects of this question or on the different classical views which have been maintained with regard to it. In this latter form of seminar all students report at every session, instead of devoting an entire session to one or two reports.

Research Courses.—The minimum requirements for the Ph.D. are generally two years' attendance and the thesis. As the topic of the thesis seldom falls within the subject of a regular seminar course, the student misses any direct help in the preparation of his thesis. For this reason, some graduate schools have instituted research courses in which the student individually reports to the professor in charge of his field of inquiry.

In some of our graduate schools, instructors and advanced students meet from time to time to discuss philosophic problems of current interest. More often a journal club is formed in which the different members report on recent publications in the field of philosophy. Many of our universities make provision for the publication of philosophical studies. They are generally devoted to the publication of theses or syllabuses by the professors.

Philosophy in the German Universities.—The students now entering the university from the gymnasias have had practically no training in philosophy, and the great majority of the courses are, therefore, elementary and, for the most part, historical in character. Nearly all of them are lecture courses, whether public or private, requiring no work on the part of the student except such reading as he chooses to do on his own account. The students taking philosophy belong to different groups besides those who are candidates for the Ph.D. in philosophy. Philosophy is one of the subjects of the state examination which every candidate must pass in order to teach in the

classical gymnasia. A good many of the universities still require philosophy as an additional subject (*Nebenfach*) from all candidates for the Ph.D. in the faculty of philosophy (i.e. Faculty of Arts and Sciences). Besides these, a great many people in Germany regard some university work in philosophy as essential to a liberal education, and even students of medicine, law, or technology attend many of the "public" lectures. The student has his first chance to report on his own work in the seminar which each ordinary professor gives in his field.

Courses in philosophy are either historical or systematic. Logic, epistemology, psychology, philosophy of history, ethics, pedagogy, and aesthetics form the topics of the systematic courses; but even these are largely historical. Philosophy of religion is left to the theologic faculty and philosophy of law to the faculty of law. In the reaction against the post-Kantian systems which ruled in Germany in the first half of the nineteenth century, the predominant interests developed were the epistemologic and the historical, and they are still foremost.

The requirements for the doctorate are the oral examination and the thesis, which is also most frequently historical. The fact that a doctorate is given with various grades, *cum laude*, *magna* and *summa cum laude*, makes it rather easy to get the degree with a merely passing mark. The result is that Germany grants more degrees in philosophy than any other country. The doctorate dissertation itself has been the subject of a great deal of criticism on the part of thoughtful German teachers, because, owing to the historical tendency, most students spend all their time in mere reading and senseless amassing of quotations. (See Paulsen's *German Universities*.) A great deal of criticism has also been directed against the extensive use of the lecture system. The appropriateness of the lecture in an age of quick printing has been questioned, especially by non-academic philosophers (E. von Hartmann).

Philosophy at Oxford and Cambridge.—Philosophic instruction at Oxford and Cambridge is nearly all undergraduate. At Oxford philosophy is required only of those who take the examination for final honors in *Literæ Humaniores* ("Greats") and at Cambridge of those who prepare for the Moral Science Tripos. Only a little logic is required of passmen.

At Oxford philosophy is viewed simply as part of a classical education in the liberal arts. The content of philosophic study continues the humanistic tradition, and centers itself in Plato's *Republic* and Aristotle's *Ethics*, and the logical, metaphysical, ethical, and political questions they raise. No interest is taken in the history of philosophy; and medieval philosophy is entirely unknown in the University

of Duns Scotus, Roger Bacon, and William of Occam. Of modern English philosophy only Bacon's *Novum Organum* is required. Though Hegelian philosophy has been very influential at Oxford in the persons of T. H. Green, Wallace, and Caird, Hegel has not figured in the official instruction given by the university.

In Cambridge the study of mathematics and physics has absorbed the vitality of philosophy. The Cambridge Platonists, a group of Neo-Platonic philosophers of the latter part of the seventeenth century, seem to have exerted no lasting influence on the University. Locke and Clarke were studied during the eighteenth century, but no importance was attached to such studies. Due largely to Paley, moral philosophy and natural religion were added to the regular examinations in 1779, and Paley's *Moral and Political Philosophy* became a standard textbook. In 1850 the Moral Science Tripos was instituted, largely through the efforts of Whewell, but it did not confer a degree till 1860. The Moral Science Tripos is somewhat more systematic than the philosophic portion of the examination in *Literæ Humaniores*, but success in it does not carry the *éclat* that goes to the student in the Classical or Mathematical Tripos.

Lectures at the various colleges are given by professors, lecturers, or readers, on the topics covered by the examination papers, but there is no discussion at these lectures, nor is there any task imposed on the student. Indeed, those lecture courses are simply supplemental to the real work of instruction given by the tutor. Students report weekly to their tutor, discuss their difficulties with him, and submit their essays to his criticism. The mode of life at both these universities is also conducive to a great deal of vigorous discussion among the students.

The advantage of the comprehensive final examination in philosophy is that the student cannot pass off his courses one after another (which can be done on the basis of piecemeal knowledge), but, instead, has to keep all his studies together throughout the entire period of study (about two years and a half). This undoubtedly is conducive to a genuine philosophic attitude in which the different portions of the field are compared, coordinated, and synthesized. At the same time Oxford and Cambridge teachers generally recognize that study with constant reference to certain questions to be asked on an examination is bound to be narrow and "calculated to forfeit the native instinct of curiosity of which, as Aristotle says, philosophy was born" (Mark Pattison). "It would be difficult for Aristotle himself to obtain a serious audience of undergraduates unless his teaching was understood to 'pay' in some Tripos" (Professor Sidgwick). The effort to win honors in a final examination is more likely to develop skill in answering

certain questions than genuine philosophic insight.

Graduate study in philosophy may now be pursued at Oxford by those who enroll as candidates for the B.Sc. degree. But the number of such students is very small, and no special courses are given for their benefit. They simply pick out, subject to the approval of the governing committee, a series of courses from those given to undergraduates, and submit a final thesis.

Philosophic instruction in Dublin University is modeled on the Oxford and Cambridge plan.

The Scotch Universities.—Philosophic instruction in the colleges of the Scotch universities is given in regular classes, somewhat as in the American college. The tendency in the Scotch college, however, is to concentrate the philosophic teaching in one year and not subdivide it into fragmentary courses, except that additional courses are given for honor students. The regent or tutorial system was abolished at the beginning of the eighteenth century (though some of the professors continued to be called regents until the middle of the nineteenth century).

Owing to excessive religious division which, for historical reasons, arose between Catholics and Protestants, Episcopalians and Presbyterians, Established and Free Churches, the Scotch people have developed a keenness for controversy and an ability to trace subtle intellectual distinctions. Philosophy has, therefore, always been a favorite study with them, and they have developed their own national philosophy, which, however, has been profoundly influenced by German idealism. More than any other English-speaking people, they have developed the study of the philosophy of law.

Most of the Canadian, Australian, and even the newer English universities resemble the Scottish universities more than they do Oxford or Cambridge in their organization of philosophic instruction.

The French Universities.—Elementary instruction in philosophy is given in the last year of the lycée or collège—corresponding to the American high school. The graduate receives his baccalaureate degree and is then allowed to choose his professional course. Some students, however, attend courses in the faculty of letters or science before entering on their professional studies. In addition to the doctorate in philosophy, the various state examinations for the licentiate, and especially for the “*agrégation*,” also require a good deal of philosophical knowledge. In the *Ecole Normale* two years of philosophy are required of all intending to qualify as teachers of history and letters, and additional special instruction is given to those who want to teach philosophy in the secondary school.

The French universities are literally and

primarily so many faculties, i.e. groups of professors. The primary duty of the professor is to advance his subject, and for this reason he gives a course or two every year. They generally take the form of lecture orations to which the public is admitted practically free. Seminar courses are given for the benefit of candidates for the Ph.D. The standard for the doctorate is much higher than that of Germany. Not only the thesis but the oral examination before conferring the doctorate is taken very seriously by all concerned and is generally reported in the *Revue de métaphysique et de morale*.

In France, philosophy is closely associated with psychology, sociology, and the philosophy of law. In no other country is there less pedantry or more scientific spirit in the teaching of philosophy, while attention to clearness and logical form is still maintained.

The Neo-Scholastic philosophy is vigorously developed in the Catholic schools and has several notable periodicals for its organs. It is characteristic of the status of French philosophy that in the Institute of France it is represented in two sections of the *Académie des Sciences Morale et Politique*.

Philosophy in Other Universities.—French positivism is still a vital force in the teaching of philosophy in Italy, Spain, and Spanish America, especially Mexico. In Italy positivism has to meet not only scholasticism and the native Catholic philosophy (Rosmini, Mamiani, etc.), but also adaptations of German idealism. In Spain and Mexico, however, the issue is sharply drawn between positivism and scholasticism; while in countries like Argentine and Chile, French positivism seems to hold the field.

Philosophy in Secondary Schools.—In Germany—The study of logic, as we saw above, formed part of the curriculum of secondary schools from the very beginning. It was kept in the curriculum of the grammar school by Sturm, Ratke, and Comenius; and Luther, with all his hatred of Aristotle, saw the value of uniting the gospel with the Aristotelian logic as a weapon against the lawless vagaries of the “*spiritualists*.” The *Lehrplan* of Francke (1698) provides for six hours a week of philosophy to prepare students for the university, and in the *selecta* of the Halle pedagogium, metaphysics, and natural law were taught in addition to logic. J. A. Ernesti and Gesner lectured on psychology, logic, natural theology, metaphysics, and ethics, and embodied them in their manuals for secondary schools (1736 and 1756). Frederick the Great and his minister of education, Zedlitz, emphasized the value of logic as an aid to independent thinking. In their school for young nobles they introduced the history of philosophy, natural law, and psychology, which were taught four hours per week for the last three semesters. The breakdown of the Wolfian

philosophy through Kant left no settled philosophic doctrines which could be dogmatically taught in secondary schools. Hence philosophy was gradually discontinued, and the original plan of the Prussian gymnasias of 1812 made no provision for it. Repeated complaint, however, was made by the university professors that students coming from gymnasias were entirely unprepared for university lectures on philosophy. In 1825 the minister of education, von Altenstein, after obtaining the opinion of Hegel, issued an order intended to remove this sharp cleft between the gymnasias and the universities. It provided for an introduction to philosophy by means of logic and empirical psychology to be taught two hours per week in the last two years. Systematic philosophy and its history were expressly excluded.

The ministerial order of 1825 did not make the teaching of this philosophic propædæutic obligatory, since teachers were not everywhere available for this purpose. In 1837 the subject was made obligatory on all gymnasias, and it was ordered that teachers of mathematics and physics be assigned to teach it. This last arrangement proved unsatisfactory. Thus the leading and most satisfactory textbook of logic, designed as an introduction to philosophy, was Trendelenberg's *Elementa logices Aristotelicæ*, which involved difficult Greek. The collapse of the great post-Kantian systems, and the growing contempt for philosophy which characterized the middle of the nineteenth century, caused other studies to crowd out the philosophic instruction. In 1856 the number of hours to be devoted to philosophic propædæutic was reduced to one in each of the last two years, and it was associated with instruction in German. This reduction from the rank of an independent study caused it to be neglected, and in 1882 it was made optional. The official *Lehrplan* of 1891 still considers it important that the student should become familiar with the more important "general concepts and ideas," but German prose readings might serve as the means. The last official order on this point (1901) leaves the situation unchanged. The director may, if he is so inclined and has a suitable teacher, give this course; but the crowding of the curriculum with prescribed work, the general attitude to philosophy, and the difficulty of finding teachers who can teach both German and philosophy has caused the distinctive course in philosophic propædæutic to fall into general disuse in Prussia, Saxony, and other German states.

In Austria, and in some of the southern German states like Baden, philosophic propædæutic is still taught. In Austria it was introduced in 1849 by Exner and Bonitz, who followed Herbart's plan. Psychology, logic, and a little of the history of philosophy are taught two hours per week in the last two

years. In Baden, the same order is followed, but the course is reduced to one hour per week. Hungary and the Scandinavian countries, in the main, follow the Austrian system.

In France.—French secondary schools are now no longer regarded simply as preparatory schools, but as schools of liberal culture. Hence philosophy is not taught in them simply as propædæutic, but to provide insight into the problems at the basis of civilization, especially the scientific problems. The basis of the present instruction in philosophy was laid by Cousin, who as minister of public instruction made Eclecticism a sort of state philosophy. The Revolution of 1848 was hostile to this state philosophy, and the reaction which followed was equally so; but Duruy restored it in 1863. Under the Duruy régime philosophy in the lycées included introduction, psychology, logic, ethics, theology, and the history of philosophy.

Under the present arrangement students are divided in the last year into two forms,—the philosophical and the mathematical. The former devotes eight and one half hours per week to philosophy and the latter only three. The official requirements in the former course include (1) introduction to philosophy, (2) analytic psychology, (3) a little of the elements of æsthetics, (4) logic and the methodology of the mathematical, the physical, and the moral and social sciences, (5) ethics, personal and social, and (6) metaphysics, covering the questions of the value and limits of human knowledge, the problems of matter, soul, God, etc. In addition four texts, chosen from a long list of ancient and modern authors, are read and discussed in the classroom, and used as the basis for the exposition of the philosophic systems which they represent.

In the mathematical form, only the logic and the ethics are developed. The close relation between the study of the methodology of the sciences and the student's other scientific studies, makes this course more popular with students than the larger course in the philosophical form. A thesis in philosophy is required for the baccalaureate only in the latter form.

Philosophy in the Secondary Schools of Other Countries.—In Italy the organic law of 1859 (law of Casati, § 188) made philosophy an essential part of the curriculum of the *licei*. Four hours are now devoted to it in the last year, and the subjects covered are mainly logic and psychology as taught in the French schools. Many, however, are urging its extension. (See *Dizionario di Pedagogia*, art. "l'Insegnamento della Filosofia.") The French system of teaching philosophy as a branch of liberal culture in the secondary schools is followed, on a somewhat reduced scale, in Argentine and Chile. For the philosophic teaching in the Jesuit schools, see article JESUIT EDUCATION. M. R. C.

PHILOSOPHY OF EDUCATION.—Relation of Philosophy and Education. — A clear conception of the nature of the philosophy of education in distinction from the science and principles of education is not possible without some antecedent conception of the nature of philosophy itself and its relation to life. Is philosophy capable of being generated and developed without any reference to education? Then a philosophy of education will be simply the application to educational ideas of an outside ready-made standard of judgment, with all its dangers of forcing the facts of education so that they conform to and support the philosophy already formed. In this case, we shall have as many philosophies of education as are required to illustrate divergent philosophic systems. The case will stand quite otherwise if there is an intimate and vital relation between the need for philosophy and the necessity for education. In this case the philosophy of education will simply make explicit the reference to the guiding of life needs and purposes which is operative in philosophy itself. It will not be an external application of philosophy, but its development to the point of adequate manifestation of its own inner purpose and motive. While different philosophies of education will still exist, they will not be so many corollaries of divergent pure philosophies, but will make explicit the different conceptions of the value and aims of actual life held by different persons. It will be seen that different philosophies exist because men have in mind different ideals of life and different educational methods for making these ideals prevail. The chief point of this article is to develop the conception of the internal and vital relation of education and philosophy.

Every seriously minded person may be said to have a philosophy. For he has some sort of a working theory of life. He possesses,

in however half-conscious fashion, a standpoint from which weight and importance are attached to the endless flow of detailed happenings and doings. His philosophy is his general scheme and measure of values; his way of estimating the significance that attaches to the various incidents of experience. If pressed to state and justify his working principle, he might reply that while it would not satisfy others, it served its owner and maker. No individual, however, is so eccentric that he invents and builds up his scheme except on general pattern that is socially transmitted to him. The exigencies and the perplexities of life are recurrent. The same generic problems have faced men over and over; by long-continued coöperative effort men have worked out general ideas regarding the meaning of life, including the connections of men with one another and with the world in which they live. These conceptions are embodied not only in the codes of moral principles which men profess and the religions in which they find support and consolation, but in the basic ideas which have become commonplace through their very generality: such ideas as that things hang together to make a world; that events have causes; that things may be brought into classes; the distinctions of animate and inanimate, personal and physical, and so on throughout the warp and woof of our intellectual fabric. Philosophy aims to set forth a conception of the world, or of reality, and of life which will assign to each of these interests its proper and proportionate place. It aims to set forth the distinctive rôle of each in a way that will harmonize its demand with that of other ends.

Need of a Philosophy of Education. — Three classes of motives, unconsciously blended with one another, usually operate in making the need for systematic and rational ideas felt, and in deciding the point of view from which the need is dealt with. These motives are the conflict of conservative and progressive tendencies; the conflict of scientific conceptions of the world with beliefs hallowed by tradition and giving sanction to morals and religion; and the conflict of institutional demands with that for a freer and fuller expression of individuality. (1) Some philosophies are marked by a reforming, almost revolutionary, spirit. They criticize the world and life as they exist, and set in opposition to them an ideal world into conformity with which the existent scheme of things ought to be brought. Other philosophies tend rather to justify things as they are, pointing out that if we penetrate to their true nature and essential meaning, each class of things is found to serve a necessary purpose and embody a necessary idea. Plato and Aristotle, Fichte and Hegel, for example, are all of them classified as idealists, but the tendency of Plato and Fichte is to set up an ideal over against

the actual; while that of Aristotle and Hegel is to exhibit the rational nature or ideal already embodied in the actual — a difference that clearly corresponds to the ordinary division of men into reformers and conservatives.

(2) Different philosophers interpret their material very differently according to the respective weight they instinctively attribute on the one hand to scientific conceptions of the world, and on the other to ethical tendencies and aspirations. If one takes his departure from the former, he will explain men's moral and religious beliefs on the basis of the principles furnished by contemporary science, and will deny the validity of all ideas, no matter how influential in life, that do not harmonize with these principles. To others, men's moral aims and efforts are the most significant thing in life and are taken as the key to the nature of reality. The results of science are reinterpreted to bring them into line. During the rapid development of natural science since the seventeenth century, many philosophies have thus made it their chief business to provide a view of reality in which the seemingly divergent claims and standpoints of natural science and morals should be reconciled.

(3) The third moving force concerns the value attached to the principle of free individuality — individuality that confers upon each person a distinctive worth not supplied by any other person and not capable of being summed up or exhausted in any general formula or principle. Some thinkers start by natural preference with the standpoint of law or a general order, or a pervasive and unifying force. Strictly individual traits are then brought into line by reduction (or at least approximation) to the universal. If individuality is not denied as an ultimate reality, it is explained and justified from the standpoint of a comprehensive uniform principle. Such philosophies tend to be deductive in character and to assign greater value to reason, which deals with general conceptions, than to perception, which reveals particulars. Persons with a strong interest in individuality reverse the standard of value and the method of consideration. Specific individuals are taken to be the primary facts; general principles, laws, classes, are derived from comparison of the individuals or are subordinate to them. In method, such philosophies tend to be empirical and inductive, accepting the observations of sense and the particular situations of conduct as the most certain data, and employing rational conceptions only as secondary means of connecting particulars or filling their gaps.

The totality or completeness at which philosophy aims is not quantitative; it is not the greatest possible sum of accurate knowledge. As to this sort of completeness or wholeness, philosophy cannot compete with the special sciences taken in their totality. For all its special facts, philosophy must depend upon

these sciences, and so far as organization of the facts into a larger system of knowledge is concerned it must also walk humbly in the path beaten by science. But there is another kind of unity and wholeness with which science is not concerned: unity of attitude and wholeness of outlook. But wholeness means also balance, interaction, and mutual reinforcement of the various values and interests of life: religion, poetry, industry or the business of making a living, politics or the art of living together, morals, science itself. An account of "experience as a whole" is a conception of experience that shows the special contribution which each of these typical interests makes, and the claim for recognition it may legitimately put forth. The only "experience as a whole" that concerns man is an experience whose parts change continuously, but all change into one another as there is occasion, with ease and flexibility, and so as to enrich one another. Its opposite is not our everyday experience with its fluctuations and its endless running out into the new, but one-sided exaggerations of some phase of this everyday experience, or an isolation of its interests so that they restrict one another, and thus impoverish life.

Philosophy of Education, Science of Education, and Principles of Education.—Education is such an important interest of life that in any case we should expect to find a philosophy of education, just as there is a philosophy of art and of religion. We should expect, that is, such a treatment of the subject as would show that the nature of existence renders education an integral and indispensable function of life. We should expect an interpretation and criticism of the materials and methods currently used in education, using this necessary function as the standard of value. Such a treatment is usually presented under the title of "Principles of Education." While no rigid line marks off this discussion from what is termed the "Science of Education," there are differences of aim and spirit that are worth noting, because of the light they shed upon the nature of a philosophy of education. It is possible to start with education as an established fact, with education as it is currently practiced, and to describe and analyze the various factors that enter into it, factors of school organization and administration, of management and discipline, of instruction and the various branches of study. So far as the analysis reveals general principles of individual growth and of social grouping which are operative in the degree that teaching and training are effective, its result rises above the level of recounting and cataloguing relevant phenomena. Hence it deserves the name of a science. This science affords the basis for a critical comparison of the various processes that are currently employed. As teachers are put in intelligent possession of it, their own work becomes less

blind and routine; the science, as in other cases, develops a corresponding art which lifts its practitioners from artisans into artists.

Notwithstanding its intellectual and practical value, such an account of education does not cover the whole ground. It works, so to speak, inside of education as a given fact. Another and larger view is possible and desirable, a less professional and a more human view. Education is a concern not merely of school administrators and teachers, of pupils and their parents, but of society. We may have a definite and systematic knowledge of the principles that are at the bottom of the most effective current practice of the day, and may be able to use this knowledge to criticize and correct defective phases of this practice, and yet be thrown back upon mere opinion or mere custom for a judgment as to the value of an educational system as a whole. The general spirit and trend of an established education might be wrong, and yet make possible a scientific account of itself which would be available for rectifying it in details. But the improvement would still be within a scheme which in its main direction and purport was not what it should be.

We have to judge every educational institution and practice from the standpoint of that "whole of experience" which calls it into being and controls its purpose and materials. There exist not merely the principles by which the existing system of education is made effective, but also the principles that animate the entire range of interests of the whole life of the community and that make the existing system what it is. An interpretation and valuation of the educational system in the light of this inclusive social context is the larger and more human view of which we spoke. It utilizes the contributions of science in all its branches to give society an insight into what sort of thing it is undertaking in the training of its members, and it gives society a clearer consciousness of the meaning of the educational office so largely performed by instinct and custom.

Philosophy is the General Theory of Education.—The connection of education and philosophy is, however, even closer and more vital than this sketch of the principles of education, as distinct from the science of education, would indicate. *Philosophy may be defined as the general theory of education*; the theory of which education is the corresponding art or practice. Three interlinked considerations support this statement: (i) Men's interests manifest their dispositions; (ii) these dispositions are formed by education; (iii) there must be a general idea of the value and relations of these interests if there is to be any guidance of the process of forming the dispositions that lie back of the realization of the interests. (i) If at any time the various values of experience are out of harmony with

one another, the ultimate cause of the difficulty lies in men's habitual attitudes toward life: the habits of judging and of emotional appreciation that are embodied in their habits of action. Interests, attitudes, dispositions, fundamental habits of mind are mutually convertible terms.

(ii) If we but consent to extend the term education beyond its narrow limitation to schooling, we shall find that we cannot stop short in this extension till we have broadened it to cover all the agencies and influences that shape disposition. Not merely books and pictures, but the machinery of publication and communication by which these are made accessible must be included — and this means the use made of railway and telegraph as well as of the printing press, the library, and the picture gallery. Ordinary daily intercourse, the exchange of ideas and experiences in conversation, and the contacts of business competition and coöperation are most influential in deciding the objects upon which attention is fixed and the way in which attention is given to them. Every place in which men habitually meet, shop, club, factory, saloon, church, political caucus, is perforce a schoolhouse, even though not so labelled. This intercourse is in turn dependent upon the political organization of society, the relations of classes to one another, the distribution of wealth, the spirit in which family life is conducted, and so on. Public agitations, discussions, propaganda of public meeting and press, political campaigns, legislative deliberations, are in this regard but so many educational agencies. In brief, every condition, arrangement, and institution that forms the emotional and imaginative bent of mind that gives meaning to overt action is educational in character.

(iii) There are but two alternatives. Either these agencies will perform their educational work as an incidental and unregulated by-product, molding men's mind blindly while conscious attention is given to their other more tangible products; or men will have an idea of the results they wish to have attained, will judge existing agencies according as they achieve or come short of these ends, and will use their idea and their estimate as guides in giving the desired direction to the working of these agencies. This brings us, again, to philosophy, which, as we have seen, is the attempt to develop just such an idea. This is what is meant by saying that philosophy is, in its ultimate extent, a general theory of education; or that it is the idea of which a *consciously guided education* is the practical counterpart.

It is, of course, possible to exaggerate the importance of philosophy even when it is conceived in this vital and human sense. Reflection is only one of the forces that move our action, and in the thick of events it gives place to necessities of more urgency. But on the other hand, reflection is the only thing

that takes us out of the immediate pressure and hurly-burly of overt action. It is a temporary turning aside from the immediate scene of action in order to note the course of events, to forecast probable and possible issues, to take stock of difficulties and resources, to bring to explicit consciousness evils that may be remedied, to plan a future course of action. Philosophy cannot create values by thinking about them, by defining and classifying and arranging them. But by thinking about them, it may promote discrimination as to what is genuinely desirable, and thereby contribute to subsequent conduct a clearer and more deliberately settled method of procedure in attaining what is desired.

There is always danger that the student of philosophy will become simply a student of philosophic traditions, of something that is conventionally called philosophy but from which philosophic life has departed because the genuine problem in life which called out the formulation has departed from consciousness. When philosophic distinctions are approached from the standpoint of their bearing upon life through the medium of the educational process in which they take effect, the perplexity, the predicament, of life which generates the issue can never be far from recognition.

Relation of the History of Philosophy to Education. — The conception of the intimate connection of philosophy with the fundamental theory of education is borne out by reference to the history of philosophic thought. So far as European history is concerned, philosophy originated at Athens from the direct pressure of educational questions. The earlier philosophy, that of the Greek colonies, was really a chapter in the history of science, dealing with the question how things come to be what they are and how they are made. Then the traveling teachers, known as the Sophists, began to apply its results to the conduct of life, and to use the same methods to discuss moral and social matters. Up to their time, men had attained skill and excellence in the various callings of life and in the business of citizenship through apprenticeship in the customs of the community. The Sophist professed to be able to teach "virtue"; that is, ability in the various functions of life. Some limited their claims to ability to teach the arts of poetry and oratory; others gave instruction in the various industrial arts or in military tactics. Others broadened these pretensions, professing ability to convey power in the management of human affairs, private, domestic, and public. It is impossible to exaggerate the historic significance of these claims. They implied that matters which had always been left to practice, and to practice controlled by the habits and ideals of the local community, could be set free from their customary provincial setting and be taught on theoretical grounds, on grounds of intellect. Natu-

rally these pretensions evoked violent protests from conservatives, who felt that the life of the community was at stake. This conflict of devotion to social customs with a reliance upon abstract knowledge provoked the first great speculative issues. What is the real basis of social organization and of moral responsibilities? Do these rest upon custom, upon enactment by superiors, or upon universal principles of nature?

At first these questions were discussed, as was natural, in a casual and superficial way. But Socrates, Plato, and others disentangled the basic questions involved. What is the nature of the state and of law? What is the true end of life? How shall man know this end? Can virtue or excellence be taught? Is it a matter of practice and habit, or something intellectual—a kind of knowledge? If so, what kind? What is knowledge? What is its standard? If virtue can be learned, how is learning related to knowledge?

These questions might be multiplied almost indefinitely, but it is more profitable to note that they tended to group themselves into three main problems: (i) What is the relation of knowledge, of reason, to practice, custom, and the opinions that go with custom? (ii) What is the relation of human life, especially of social organization and its virtues and responsibilities, to the nature of the universe, of reality itself? (iii) What is the relation of change, and of the particular things that change, to the universal and permanent? In a generation or two these questions were largely cut loose from their original connection with education. Their discussion developed into distinct disciplines, often isolated from reference to practical or social matters: into logic, as a theory of knowledge; into metaphysics, as a definition of the nature of things; into cosmology, or a general account of the constitution of nature. But the fact that the stream of European philosophic thought arose out of the discussion of educational ends and means, remains an eloquent witness to the ulterior motive and purport of philosophic reflection. If philosophy is to be other than an idle and unverifiable speculation, it must be animated by the conviction that its theory of experience is a hypothesis that is realized only as experience is actually shaped in accord with it. And this realization demands that man's dispositions be made such as to desire and strive for that kind of experience. The philosophy of education is not the external application to educational affairs of a conception of reality ready made independently of education; it is just the philosophic conception of a balanced and articulated experience stated so as to be available for shaping intellectual and emotional disposition, so that the existence it describes may become a living fact, not the dream of a philosopher's brain.

Problems of Philosophy and of Education

the Same.—Since upon education falls the burden of securing the practical realizing and balancing of the various interests of life, the educator faces, if only in half-conscious, unsystematic form, precisely the same questions that philosophy discusses in the abstract. In the attitude taken to matters of hygiene, physical training, manual training, corporal punishment, etc., there will be expressed, for example, some idea of the connection, or lack of connection, of mind and body, an idea that, made explicit and fitted in with other beliefs, corresponds to some typical philosophical theory of the relation of bodily and mental action. Some practices imply that man is an external compound of body and soul, in themselves two independent forces. Others proceed on the assumption that the body is a temporary shell in which mind is housed, or that the body is a clog upon the development of spirit. Other projects imply that only through the adequate functioning of the bodily organs can there be realized a symmetrical and sound mental life. The various theories held by philosophers as to the relation of knowledge to practice are paralleled in educational procedure. Some assume that contemplative knowledge is an end in itself; others, that knowledge is a mere external prerequisite for successful action, success being measured on the basis of material possessions and power; others that knowledge is an intrinsic condition of a practice that is free and full of meaning. In educational discussion, one or other of these ideas appears in some disguised form in every dispute about cultural *versus* professional or vocational education, and shows itself in most debates concerning the relation of the acquisition of knowledge to the formation of character. The old (almost the first) philosophic question as to the relation of the individual to the established objective order appears in instruction as the question of individual initiative and choice over against the accumulated body of organized knowledge which forms the ready-made subject matter of teaching. The philosophic controversy as to the method of knowledge, with its division of camps into sensationalist and rationalist, has a counterpart in the different methods of learning that are encouraged in schools. The philosophic split between mind and physical nature corresponds to the educational antagonism of humanistic and scientific studies, which also has a genuine, even if indirect, bearing upon the philosophic issue of idealism *versus* realism.

To sum up: Various partial tendencies and interests of life are reflected in native home-spun intellectual schemes possessed of strong emotional coloring. These are traditionalized; they float, so to speak, upon the institutions of a society, giving them their sanction and explanation. Philosophies in the formal and technical intellectual sense are generated when these traditional systems are sub-

jected to independent intellectual examination with a view to their rational criticism and supplementation. As the more popular schemes express the standard and the subject matter of the educational procedures of a community, since they naturally aim to shape disposition in the continued acceptance of the customary beliefs and ideals,—so the more conscious philosophies can be tested and objectively embodied only as they are made the working bases of educational processes that develop an experience in harmony with themselves. To convince a small number of the theoretical soundness of the philosophy, while men's lives are still ordered in the mass upon quite another basis, furnishes such a contradiction of the claim of the philosophy to evaluate "experience as a whole" as to place the latter in a ludicrous position.)

Character of the New Philosophy of Education.—Every generation and period has its own special problems which decide where the emphasis is thrown. When social conditions and scientific conceptions and methods are both in a state of rapid alteration, the tendency to philosophic reconstruction is especially marked, and the need of working out the newer point of view so that it will throw light upon the spirit and aims of education is especially urgent. The present time is characterized by at least three great movements, of which education must take account in the most radical way if it is to bear any relation to the needs and opportunities of contemporary life—and otherwise intellectual and moral chaos must be the result. These movements are: (i) the rapid growth of democratic ideals and institutions; (ii) the transformation of industrial life—the economic revolution that began in the later eighteenth century with the application of steam to manufacturing and commerce; (iii) the development of *experimental science*, culminating in the idea of evolution and the thoroughgoing modification of older beliefs about the processes and organs of life.

(i) The democratic movement radically influences education if only because it inevitably produces the demand for universal education. It is impossible that the type of education adapted to the small class in aristocratic and feudal societies, that alone had an opportunity for an intellectual culture, should be adapted to the needs of a democratic society which demands the development of all. By no possibility could the education of a class become the education of all, for a class education is made what it is by the exclusion of most of the people from the opportunities for which it prepares. A democracy, moreover, signifies a social organization which is maintained, upon the whole, by the voluntary wish of the mass of the people, and which is responsive to changes in their purposes. This implies a much greater dependence upon the

intelligence and sympathetic good will of all the members of society than is required in communities where authority and precedent are the mainstays of social arrangements. A distinct type of education is demanded to meet the need for individual freedom and initiative combined with respect for others and an instinct for social unity.

(ii) The industrial revolution, with the changes it brought about in modes of association, habits of mind, and increase of commodities, is both cause and effect of the democratic development. From every standpoint it exacts modifications of educational ideas and practices. The importance of labor which it proclaims is a note new in the world's history. The effect of the new inventions in eliminating distance and bringing all mankind within the same circle makes interdependence, which had been preached as an ideal, an operative fact. Since the new industrial régime depends upon the application of science to the control of natural forces, men's best and truest knowledge of nature is put in effective circulation. Men's actions are servile or intelligent according as men do or do not have an appreciation of the ideas which govern their occupations. The extreme specialization and division of labor tend to make men simply small parts of the machines they tend, and only the forethought and oversight of education can avert this menace. The multiplication of material goods makes necessary a higher æsthetic taste to prevent general vulgarization. It also affords new opportunities to the masses which they must be educated to take advantage of. Conversely, the luxury and kind of leisure that had been tolerable or even graceful in past régimes becomes a social menace when the social mechanism makes the responsibilities of production and consumption more and more important.

(iii) Philosophers have debated concerning the nature and method of knowledge. It is hardly cynical to say that positiveness of assertion on those points has been in proportion to the lack of any assured method of knowing in actual operation. The whole idea and scope of knowledge-getting in education has reflected the absence of such a method, so that learning has meant, upon the whole, piling up, worshipping, and holding fast to what is handed down from the past with the title of knowledge. But the *actual practice of knowing* has finally reached a point where learning means discovery, not memorizing traditions; where knowledge is actively constructed, not passively absorbed; and where men's beliefs must be openly recognized to be experimental in nature, involving hypothesis and testing through being set at work. Upon the side of subject matter, the ideas of energy, process, growth, and evolutionary change have become supreme at the expense of the older notions of permanent substance, rigid fixity,

and uniformity. The basic conceptions which form men's standards of interpretation and valuation have thus undergone radical alteration.

Even this bare sketch should suggest the new forces at work in education, and the need of a theory corresponding to the new attitudes and tendencies of our times, if the present situation is to be approached in a spirit of clear intelligence. We need to know the difference that the democratic ideal makes in our moral aims and methods; we need to come to consciousness of the changed conception of the nature of existence that its spread imports. We must reckon intelligently with the new and gigantic industrial forces that have come into being, securing by education a disposition to subordinate them to general welfare and to equality of opportunity so that they may not plunge us into class hatreds, intellectual deadness, and artistic vulgarity. Unless our science is to become as specialized and isolated a thing as was ever any scholastic scheme whose elaborate futility we ridicule, we must make the experimental attitude the pervasive ideal of all our intellectual undertakings, and learn to think habitually in terms of dynamic processes and genetic evolution. Clearness upon the issues, problems, and aims which our own period has brought to the foreground is a necessity for free and deliberate participation in the tasks that present-day education has to perform. Attaining this clearness, with whatever revision of stock notions it may entail, is the peculiar problem of a contemporary philosophy of education. J. D.

For the actual plan of the study of the Philosophy of Education, in the modern curriculum, see EDUCATION, ACADEMIC STUDY OF.

PHOBIA.—A fear, of the nature of a delusion (*q.v.*), a fixed idea (*q.v.*), or an obsession (*q.v.*). The more common phobias are: pyrophobia (fear of fire), claustrophobia (of closed places), agoraphobia (of open places), and mysophobia (of dirt). S. I. F.

PHONETIC METHODS.—See READING, TEACHING BEGINNERS; SPELLING, TEACHING OF.

PHONETICS.—Judged by its derivation, the word "phonetics" should mean the science of sound. Among teachers of languages, however, it is restricted to the science of speech sounds of human beings. Considered in this manner, phonetics is usually divided into two main divisions: the acoustic and the organic. The former is generally classed with physics, since it concerns the sounds of speech as sounds, independently of their origin or mode of formation. The latter could be classed with physiology (*q.v.*), though it is, generally speaking, given over to students of languages and philology (*q.v.*). It will appear later, however, that experimental phonetics, the most recent of the branches of the science to develop, overlaps these divisions, and is at the same time "physical," physiological, and philological.

Historical.—The earliest studies of phonetics of which we have any knowledge were theoretical. The Sanscrit grammarians seem to have been remarkable phoneticians, as were later the grammarians of Alexandria. It is to the desire of the latter to represent accurately the Greek vowels that we owe the introduction of the accents which enable foreigners to pronounce Greek with less difficulty. The Roman phoneticians, though probably inferior to their predecessors, brought to bear, none the less, on the study of foreign languages, especially Greek, a fund of close observations. These observations, like others by ancient grammarians and phoneticians, frequently enable us to understand just how certain letters were pronounced. Indeed, without these data, philology could not have developed so rapidly and certainly as it has, bringing with it a flood of light concerning the ancient monuments of literature and history, whose country, age, dialect and authorship (single or composite) we are able to establish. This often overlooked side of phonetics—its power to vitalize, to give a soul to, the dead symbol or letter—has led some scholars to divide phonetics into two great divisions: the historical (which we have just mentioned), and the descriptive

or modern. History and geography, according to a remark of Louis Havet, bear somewhat the same relation to each other as these two branches of phonetics. Since the latter branch — the descriptive — is for teachers by far the more important, the present article will be devoted in the main to a consideration of this.

Descriptive Phonetics. — The descriptive branch of phonetics involves a minute study of the manner in which the sounds of living languages are produced, the nature of these sounds, and their relation to one another. This minute study makes clear to us, first, the sounds of our own language; secondly, those of other languages. We learn, for example, what distinguishes the *b* of Spanish or French from the *b* of English. By carrying this study through all the sounds of a given foreign language, we are able to pronounce it better and more intelligently, — to speak it with as little "accent" as possible. This being the case, it is evident that descriptive phonetics is of great value to scholars, teachers, students of dialects, philologists, missionaries, diplomats, interpreters, as well as to the increasing number of persons who realize that, to appreciate the literary beauties of a foreign language, one must be able to read it aloud with a very considerable degree of correct utterance.

Descriptive phonetics is one of the few strictly modern developments of science which are due to the English nation. In fact, the "English school" of phonetics is now the dominant one the world over (leaving aside experimental phonetics, of which more presently). We may therefore omit all further mention of the history of phonetics, and pass immediately to the inception of the "English school," which may be said to have begun with Alexander Melville Bell (the father of Alexander Graham Bell), who published in London, in 1867, a work called *Visible Speech* (second edition, London, 1882). Bell made what may be called an organic study of phonetics; that is, a study of the action of the organs of speech (especially of the tongue) in the production of vowels and consonants. This had of course been done many times before. The originality of Bell lay in his constructing an alphabet in which the form of the symbol should bear some indication of the position of the organs of speech. The mere appearance of the symbol was to tell how the sound was produced. The alphabet which resulted was exceedingly cumbersome, and the scholars who have ever learned to read it or write it are few in number. The importance of Bell's work lay in the impetus which it gave to succeeding scholars. His work suffers from being too theoretical. The name *Visible Speech* is in itself an instance of colossal exaggeration. Fortunately, Bell counted among his immediate followers a few men of practical sense and of sound philological knowledge, the chief of whom was Henry Sweet, professor at Oxford. Sweet and others

perfected Bell's alphabet, and carried to a very high point the minute observation of the spoken word. Their study of the tongue positions for the vowels was especially close, for these scholars were Englishmen, and in English the tongue is relatively of great importance while the lip action is reduced to a minimum. Bell, Sweet, and others of the English school established an elaborate system of nomenclature. They spoke of vowels as round or unround; as front, mixed, or back; as high, mid, or low; as narrow or wide. Space is lacking here to explain this terminology.

For a while, there was considerable opposition on the continent to the adoption of the English system. Germany was especially rebellious and scornful. The advance in France was rapid, largely because of the early conversion of Paul Passy. He adopted the English system, with slight modifications, but saw clearly the impossible nature of the Bell-Sweet alphabet. His wide linguistic knowledge (he has spoken from childhood four or five languages) gave him unusual advantages. His most important reform lay in the alphabet. Adopting several letters from A. J. Ellis, the author of *On Early English Pronunciation* (London, 1869), and taking some hints from Bell and Sweet, he perfected little by little what is now called the international phonetic alphabet. As the editor of the *Fonetik Tijdschrift* (founded in 1885), which became the *Maitre Phonétique* in 1889, he was in a position to offer an increasing publicity to the new alphabet. The *Maitre Phonétique* is the organ of the Association International Phonétique, the most powerful and widely diffused linguistic society in existence. As for the alphabet founded by Passy, it is rapidly becoming the phonetic alphabet of the world, and hundreds of treatises employ it. Even Germany has adopted (unofficially, of course) this alphabet for work in phonetics and modern languages.

The following table gives the phonetic symbols and their explanation according to the International Phonetic Association:—

CONSONANTS

The following letters have their usual values *b, d, f, g* (as in *go*), *h, k, l, m, n, p, r* (rolled as in Scotland), *s, t, v, w, z*.

- j* is the sound of *y* in *yes*.
- ɲ* is the sound of *ng* in *song*.
- θ* is the sound of *th* in *thin*.
- ʃ* is the sound of *th* in *then*.
- ʃ* is the sound of *sh* in *show*.
- ʒ* is a weakened form of the *ch* in German *ach*.
- ç* is a weakened form of the *ch* in German *ich*.
- ʒ* is the sound of *s* in *measure*.

VOWELS

- i:* is the vowel in Modern English *see*, but pure as in the North of England, not diphthongized as frequently in the South.
- i* is the vowel in Modern English *lip*.
- e* is the vowel in Modern English *get*.
- o:* is the vowel in Modern English *get* lengthened.
- æ:* is the vowel in Modern English *hat* lengthened.

- a is the vowel in French *pâte*.
- ɑ : is the vowel in the first syllable of *father*, as pronounced in London dialect.
- ɔ is the vowel in French *bonne*.
- ɔ : is the vowel in French *port* (i.e. ɔ lengthened).
- u : is the vowel in Modern English *too*, but pure as in the North of England, not diphthongized as frequently in the South.
- u is the vowel in Modern English *put*.

When unstressed, the vowels *ε*, *a*, *ɔ* are somewhat obscured, that is, they tend towards the neutral vowel heard in the unstressed syllables of *above*, *sofa* (modern pronunciation).

DIPHTHONGS

- iu. The sound *i* : followed by the sound *u* : the first element being stressed.
- ei. The diphthong heard in Modern English *day* as pronounced in the North of England.
- eu. The sound *ε* followed by the sound *u*.
- ai. The sound *a* followed by the sound *i*.
- ou. The sound *ɔ* followed by the sound *u*.
- ou. The diphthong heard in Modern English *go* as pronounced in the North of England.
- oi. The first element of the diphthong *ou* followed by the sound *i*.

The Scandinavian countries were among the first to accept the English school of phonetics. In this connection the celebrated Norwegian scholar Johan Storm, and Otto Jespersen of Denmark, one of the keenest and most original of living phoneticians, deserve special mention. In Germany there are at present probably only one or two phoneticians who refuse to accept the main tenets of the English school. This is largely due to Wilhelm Viëtor, who, like Passy in France, has been a potent influence of popularization of the new ideas. The English school, with its terminology, has also spread through the remainder of Europe, and has from the first been virtually the only form of instruction in America (leaving aside, of course, experimental phonetics, as will appear later). If an examination were to be made of the courses now being conducted in phonetics in this country, it would doubtless be found that, except in experimental phonetics, all of the literature used involves an acceptance of the English school. There are, none the less, many teachers of the subject both here and elsewhere who modify considerably the teachings of Sweet and his closest followers, and who do not believe that their system is a finality, because of such considerations as these: like everything of English origin the system is "insular" and lop-sided; it bears the birthmark of claiming too much for itself; it is suspiciously regular and schematic; vowels, for example, to the number of seventy-two appear in perfect regularity, like so many pigeon-holes in an enormous case; the system seems to have been laid out on paper, so much so that a scientist would declare it an admirable example of un-science.

Sound Production. — Before discussing experimental phonetics it will be well to mention briefly the manner in which speech sounds are produced. Speech is the conveyance of

thought through sounds produced by modifications of the stream of air which passes from the lungs to the outer air. It is a system of signals which have been agreed upon. If we imagine a person shut up in a windowless tower, but having access to a rubber tube through which water continuously flows from a spring in the tower to the open air outside, it will be apparent that he can devise a system of signals which can convey messages to those without. He can devise a succession of pressures and of stoppages of the tube, and his problem is not unlike that of Morse when he contrived his telegraphic code. Human speech is built on this model. In our case, however, the channel through which the air passes has fortunately a number of stops, of bifurcations, of crooks and corners. These enable us to vary to a large degree the sounds to be produced, so that we dispose of a clear, highly developed code of signals.

Speech Organs. — The main places where the column of air emitted from the lungs is modified in speech are as follows: (The column, of course, moves from within outwards, — towards the listener, — which facilitates the conveyance of signals.) The first modification of the column of air may be produced in the larynx, which is at the enlargement known as the Adam's apple. In this enlargement are two muscles, named erroneously the vocal cords, which can be held apart, as in ordinary breathing, or made to approach each other to any desired degree, even to the point of complete closure. When these muscles are touching loosely, the air may be forced between them by pressure from the diaphragm in such manner that a buzzing, which we call *voice*, is produced. If the buzzing or vibrating column of air meets no appreciable obstruction in its progress to the outer air, the sound is called a vowel; if it meets one or more obstructions, it is called a consonant. There is perhaps no briefer statement possible of the generic difference between vowels and consonants. If we limit ourselves to the ordinary European languages, there is no other place of stoppage or stricture in the passage towards the outer air, until we reach the lower fringe or edge of the soft palate. It is evident that the back of the tongue can rise against this fringe, and, by jerking away just at the instant when the air pressure is at the right degree, cause a consonant sound; or, that the tongue remaining against the fringe, the uvula (the hanging end of the soft palate) may be made to vibrate, as when children "trill" or "gargle." Again, the soft palate itself may be pressed against the wall of the throat back of it, which will close the channel into the nasal passage, or it may hang down somewhat, leaving that passage free. The former is the position of the soft palate for vowels (except, of course, nasal vowels, such as exist in French, Portuguese, and American English), and for the oral

PHONETICS

(that is, non-nasal) consonants. If now we consider the vault of the mouth, beginning just above the fringe of the soft palate and extending to the front upper teeth, we realize that the tongue can touch any part of this surface. In fact, the majority of consonants are produced against this vault. It is unnecessary to name these consonants, since any one can experiment for himself. It should, however, be remarked that the tongue is able to execute quite a varied system of "signals." It can stop the passage entirely, as in *g, k, d, t*, or nearly stop it, as in the initial consonant of *yes*, in that of *she*, in the consonant of the German word *ich*, etc. It can make its tip vibrate, as in a lingual *r*. Again, it is clear that the upper teeth offer a convenient place of partial stoppage, as in *th, f, v*; and, finally, that the lips can offer stoppage, as in *p, b, m*.

Experimental Phonetics.—Such being briefly the physical facts, phoneticians attempted to contrive instruments which would record the movement or action of the various organs. The result is the most recent development of the subject, — namely, experimental phonetics. This branch of phonetics arose in France, in a committee appointed in 1874 to examine into the possibility of employing instruments in phonetic research. The committee received encouragement from Etienne Marey, the ingenious physiologist of the Collège de France, some of whose apparatus proved of great value. One member of the committee, Dr. Rosapelly, a physician of Paris, invented several instruments of the highest utility, such as: the *trembleur*, which records, by means of an electrical connection, the vibrations of the larynx; instruments for registering the vertical movement of the larynx in speaking or singing; for recording the passage of air through the nose; for the vertical movements of the lips. Dr. Rosapelly, however, forced to give most of his time to the practice of medicine, did not long continue his career as a phonetician. His work was taken up in 1885 by the Abbé Rousselot, who then made the acquaintance of Rosapelly, Marey, and of the skillful constructor, Charles Verdin. From that time to this, Rousselot has not ceased to devote himself with enthusiasm and patience to the new science, and is considered its founder. His laboratory at the Collège de France has been and still is the best in the world, and his publications, which began in 1890, have been numerous. He has perfected several inventions of others and contrived some of his own. His pupils are numbered by hundreds and have carried his principles into many countries. His most brilliant pupil in France has been A. Zund-Burguet, who has invented several ingenious and valuable instruments. The largest courses in experimental phonetics (general phonetics as well) are those conducted by Professor Rosset in the summer school at the University of

PHONOGRAPH

Grenoble. Hundreds of students from a score of nationalities gather here every summer for the subject. The first instrument having an application to phonetics which was invented by an American was the phonograph of Edison (1877), an instrument which is simply a perfection of the phonautograph of a French printer, Scott de Ménilville (1859). The first work in experimental phonetics as such appears to have been done by Professor C. H. Grandgent, who published in 1890 an article on *Vowel Measurements* (*Publications of the Modern Language Association*). Professor Raymond Weeks contrived in 1890 an artificial vowel rounder, and later an instrument for recording the movements of the soft palate, an instrument for the vibrations of the larynx, the spiograph (which writes the varying pressure of the air in the mouth during speech), and a perfected apparatus for the movements of the lips. Professor F. M. Josselyn published, beginning in 1899, some valuable work on Italian phonetics. Professor E. W. Scripture has done exhaustive work in the tracing and study of speech curves.

There is great need of an extension of the teaching of phonetics in American institutions of learning. Not only would this aid in making philology more vital, but it would prove of the utmost value to teachers of elementary English. Strong courses should be established in all summer schools, where the eager and conscientious public school teachers would assimilate rapidly the new and vivifying knowledge of phonetics. R. W.

PHRENOLOGY.—A pseudo-science which attempts to discover the mental characteristics of the individual through an examination of the external configuration of the skull. This science was first suggested by F. G. Gall (1758–1828). It was afterwards developed by Spurzheim and others. Gall examined a large number of persons and noted their special mental characteristics as well as the configuration of their heads. His attention was especially drawn to persons of marked characteristics, such as he found in the prisons and hospitals. A man who had been confined because of his tendency to steal was evidently an interesting character for Gall, because his mental traits were clearly defined by his misdemeanors. Comparison of a number of individuals who were of this marked type led to a mapping of the outside of the skull and the designation of the various regions of the brain to which certain mental faculties were supposed to be related.

There can be no doubt that such investigations as these stimulated a discussion of the relation between mental characteristics and the development of the central nervous system. Indeed, certain enthusiastic writers have regarded Gall as the father of the modern science of cerebral localization. Gall undoubtedly suggested the possibilities of such a science, but he is in no wise responsible for the technique which was later developed and which put the whole matter on a definite scientific basis. In the form in which Gall projected the science, it was hopelessly involved in two fundamental errors. In the first place, his subdivision of mind into certain faculties was grossly inadequate. To assume that discrimination of color is a separate mental faculty, or that the faculty of reverence or veneration can be distinguished as a separate mental characteristic, shows the crudity of the psychological analysis on which phrenology is based. As a matter of fact, each of these functions is a composite including certain forms of perception, and certain forms of ideation. With the development of modern psychology, the classification of faculties proposed by phrenology has come to be entirely untenable. In the second place, it has been shown conclusively that the external configuration of the skull is no indication of the internal form of the cerebrum. Furthermore, the cerebrum has been mapped out by thoroughgoing scientific methods in such a way as to show that

the localization of functions depends upon an entirely different physiological structure from that which is assumed in the phrenological system. We may therefore say in general that with the advance of physiological knowledge the anatomical assumptions of the phrenologists have also become entirely untenable.

The pseudo-science, as cultivated to-day, is commonly employed for charlatan purposes. The practitioner announces that he is able to describe to the individual his capacities for future training and occupation. Such guesses as he is able to make with regard to the individual's characteristics are derived from a general inspection of the individual rather than from reference to the external configuration of the skull.

PHYSICAL DIRECTOR.—See PHYSICAL EDUCATION.

PHYSICAL EDUCATION.—**Historical.**—In time past and in our own time physical education has been exalted, tolerated, neglected, or denounced, according to the prevailing conceptions as to the nature of the human body and of its relations to the human mind. The character of these conceptions has depended chiefly on the ideals of human excellence held at different periods in the history of education. Those ideals, according to Hartwell, may be characterized as the Greek or æsthetic, the monkish or ascetic, the military or knightly, and the modern or scientific.

The Greek ideal recognized the unity or symmetry of body and mind as expressed by Plato in the *Timæus*. "Everything that is good is fair, and the fair is not without measure. Now, we perceive lesser symmetries and comprehend them, but about the highest and greatest we have no understanding, for there is no symmetry greater than that of the

soul to the body. This, however, we do not perceive, nor do we allow ourselves to reflect that when a weaker or lesser frame is the vehicle of a great and mighty soul, or, conversely, when a little soul is incased in a large body, then the whole animal is not fair, for it is defective in the most important of all symmetries; but the fair mind in the fair body will be the fairest and loveliest of all sights to him who has the seeing eye." Gymnastics were accorded a large and important place in the educational program of Greek youths. The teaching of gymnastics afforded positions of honor and emolument to distinguished and ambitious men. Bodily training furnished themes for poets, philosophers, and historians; sculptors and painters sought models in the gymnasium, and Greek physicians studied and adopted exercises and procedures originated by teachers and gymnasts. In the breadth and sanity of its aims, the completeness of its development as a national institution, and its abiding influence upon succeeding generations, Greek physical education has no parallel. (See GREECE, ANCIENT, EDUCATION IN.)

The ascetic ideals of the monks, which after the first few centuries of the Christian era exercised a profound influence upon European thought and life, was the antithesis of the Greek ideals of education. The conception that the soul and the body are independent and mutually antagonistic entities was responsible for the complete abandonment of physical education by the monks. They believed that all flesh was the creation of Satan and that spiritual health was best subserved by self-torture and bodily weakness. The influence of the monks continued to antagonize and retard bodily training in education until the beginning of the nineteenth century. (See MONASTICISM AND EDUCATION; MIDDLE AGES, EDUCATION IN.)

The military or knightly ideal of human excellence existed side by side with the ascetic ideal of the monks. It played a conspicuous and important part in the education of the sons of noblemen and gentle folk. The young knight was trained to ride, draw the bow, use weapons, and hunt; some attention was given to manners, but very little to letters. The aim was the development of efficient soldiers and gentlemen. This form of education was popular in England and the Continent until the seventeenth century. (See CHIVALRIC EDUCATION; GENTRY AND NOBLES, EDUCATION OF.)

Modern Views. — The modern or scientific ideal of physical education owes its origin to the belief "that to work the mind is also to work a number of the bodily organs, that not a feeling can arise, not a thought pass, without a set of concurring bodily processes." The sciences of biology, physiology, and psychology have furnished a basis for the study and application of the laws governing the growth,

development, and education of the body and mind. Man's knowledge of himself has been immensely increased and his conception of nature and his place in nature radically changed. One of the most prominent results of the progress made in these sciences is a deeper appreciation of the vital importance of motor training in education.

The modern or scientific ideal of physical education recognizes two chief aims: (1) health, normal growth and development of the body as an efficient organism; (2) psychomotor education, with emphasis on bodily control and the expression of personality or character of the individuals.

These ideals are based on the sciences of biology, physiology, psychology, and education, but physical education itself has not yet attained the dignity of a definite science. Since the somewhat crude attempt of Ling (*q.v.*) early in the nineteenth century to devise a system of gymnastics based on physiology and coordinated with educational procedure, much progress has been made in placing physical education on a scientific basis. During the period of evolution from crude empiricism to scientific principles, physical education has passed through many phases.

Three distinct systems originated in Europe and developed simultaneously; the Swedish system of educational, military, and medical gymnastics devised by Ling and his followers; the German system of gymnastics developed by Guts Muth, Jahn, and Spiess (*qq.v.*); and the British scheme of athletics and games fostered and developed in the universities and public schools. (See ATHLETICS; GYMNASTICS.) The Swedish and German systems had for their chief aim the training of strong, self-reliant, and patriotic citizens. The athletics and games of England developed naturally in response to the normal play instinct of English boys and young men.

These well-defined national schemes for physical education have survived to the present day and spread to many lands. The Delsarte system of exercises was devised by François Delsarte (*q.v.*) in Paris, about 1840, to train actors in dramatic expression. The Delsarte plan had such a limited scope that it could not gain recognition as a system of physical education.

In Colleges and Universities. — In the United States physical education had no place in our schools and colleges until the latter part of the last century. Before 1860 the population was very largely rural, the school terms were short, and a large proportion of the children obtained physical vigor and psycho-motor training from participation in the varied activities of the rural home. The need for systematic bodily training in the schools was small and its importance not recognized. A few sporadic attempts were made by educational reformers to arouse interest in some phase or other of

physical education, but without success. One of these attempts, the introduction of German gymnastics by Dr. Charles Beck, at the Round Hill School Northampton, Mass., in 1823, attracted considerable attention for a few years. The New York High School and the colleges of Harvard, Yale, Amherst, Williams, and Brown followed in 1825, 1826, and 1827. Dr. Follen (*q.v.*) and, later, Dr. Francis Lieber had charge of gymnastic instruction at Harvard College and the Boston Gymnasium. The enthusiasm then aroused by the new movement was not permanent; by 1830 physical education had been discarded as a passing fad.

During the period 1830-1850 physical education was completely neglected. The decade 1850-1860 marks the beginning of the modern revival of interest in athletics, gymnastics, and hygiene, which after twenty-five years of slow growth has since developed into a large and important phase of modern education. The nascent interest in gymnastic and athletic forms of exercise during this decade was promoted by the newly established intercollegiate contests in rowing; the organization of gymnastic societies (*Turnvereine*) by political refugees from Germany who came to this country after the revolution of 1848; the lectures and exhibitions of Dr. G. B. Windship, who advocated heavy lifting; the introduction of calisthenics (*q.v.*) by Dr. Dio Lewis; and the prominence given to topics relating to physical education by speakers at teachers' conventions and institutes, by editors of educational journals, and by public school officials.

Gymnasiums were built at Harvard, Yale, and Amherst colleges in 1860, and in the same year. Amherst organized the first college department of hygiene and physical education, with gymnastics as a compulsory branch of college work. The example of Amherst was not followed to any extent by other colleges until after 1885, but since that time the extension of the movement has been very marked, as shown by the following figures for 124 of the leading colleges in 1910:—

	PER CENT
Colleges having organized departments of	
Physical education	84.3
Colleges having gymnasiums	98.2
Colleges having swimming pools	36.6
Colleges having athletic fields	95.8
Colleges having tennis courts	97.6
Colleges having regular instruction in gymnastics	94.7
Colleges having prescribed courses in physical education	87.1
Colleges giving credit towards bachelor's degree for courses in physical education	58.2

Title of Officer in Charge of Department of Physical Education

Professor	21
Associate or Assistant Professor	4
Director of Gymnasium	38
Physical Director	20
Instructor	17
Colleges in which officer in charge of department of physical education has a seat in the faculty	75.7

Courses in physical education are prescribed for freshmen only in about one fourth of the colleges, for freshmen and sophomores in about one half of the colleges, and in about one fourth of the colleges the prescription is for three or four years. The usual credit for each year is two units or about one sixtieth of the total required credits for the bachelor's degree.

The following description of the course prescribed for freshmen in Columbia College shows in a general way what is usually taught in a college physical education course meeting two hours a week for one year:—

- (1) Physical and medical examination, 1 hour;
 - (2) instruction in track and field athletics (outdoors), 12 hours;
 - (3) instruction in marching and gymnastics, 34 hours;
 - (4) instruction in hygiene (lectures, etc.), 6 hours;
 - (5) instruction in swimming, until qualified.
- Examinations are held and students graded as in other subjects.

The typical department of physical education in the American college includes three distinct lines of activity: (1) The gymnasium and accessories, such as swimming pool, rooms for handball, boxing, fencing, wrestling, etc., in which physical education courses are conducted and the mass of students meet for general exercise; (2) the care of the students' health, which includes medical examinations, consultations, medical and surgical treatment, and instruction in hygiene and sanitation; (3) organized athletics, including intracollegiate and intercollegiate contests in the various games and sports. The forms of organization and methods of administration vary over wide limits in the colleges, but there is a marked tendency towards concentration of all the physical education, athletic and health supervision activities in one department, under the direct control of the college authorities. In this respect American colleges and universities are far in advance of similar institutions in other countries where the health, physical education, and recreations of the students are not regarded as matters for which the institutions are responsible.

In Schools.—In the private secondary and preparatory schools, physical education is organized much the same as in the colleges. The importance of motor education, health supervision, and moral education during the adolescent period is generally recognized by educators in the secondary schools. All the large schools and most of the smaller ones have well-organized departments of physical education in charge of professionally trained directors. The first attempt to include physical education in the program of the public schools was during the decade 1860-1870, when the calisthenics advocated by Dr. Dio Lewis had a wave of popularity. The interest lasted only a few years and physical education was again neglected until the decade 1880-1890, when a number of Western cities with a

large German population introduced light gymnastics of the German type in the public schools. The growth of cities, industrial development, and the rapid expansion during this period were factors in arousing the interest of educators and the public to the importance of providing physical training for the children in the schools. The city homes could not furnish the necessary environment for the normal physical development and motor training of the growing generation, and the need of modifying the school curriculum to meet the new conditions was recognized. In 1889 a conference in the interest of physical education took place in Boston. The conference was presided over by United States Commissioner of Education William T. Harris, and addresses were made by prominent educators, physicians, and specialists in physical education. The purpose of the conference was to "place before educators different systems of gymnastics and to secure discussion of the same, with a view to ascertaining clearly the needs of schools, and determining how they may best be met." A direct result of the Boston conference was the organization of a department of hygiene and physical training and the adoption of the Swedish system of gymnastics in the public schools of Boston. New York and many other cities soon followed, with the result that by 1900 nearly all the cities in the East, Middle West, and West had some form of physical education in the school program. The most common system of gymnastics in use in the school is the Swedish, or some modification of this system. A few large cities, particularly in the Middle West and Southwest, have adopted the German system.

Special directors and teachers are employed for physical training in about half of the cities where this subject is taught. The most common form of organization is a department with a director of physical training for the city, special teachers in the high schools, and supervisors in the elementary schools, who visit each class once or twice each month to criticize and help the grade teacher. The athletic activities of the school boys were developed by the boys in many cities without direction or supervision from the school authorities. Since the organization of the Public Schools Athletic League the school authorities in many cities have taken control of this important phase of physical and moral education.

Training of Physical Instructors.—The rapid growth of physical education in the schools and colleges since 1885 has been due in large measure to the development of professional schools for the training of teachers and directors of this branch of education. Between 1880 and 1900 six normal schools and as many summer schools were established for the training of physical education teachers. The course of study in the normal schools extended over two years,

including courses in anatomy, physiology, histology, kinesiology, anthropometry, hygiene, history of physical education, methods and practical work in gymnastics, athletics, and dancing. Since 1900 three of the normal schools have lengthened the course to three years, and in two of them the course leads to the bachelor's degree.

The rapidly increasing demand for teachers and directors of physical education with a good general education and professional training has led a number of colleges and universities to establish professional courses in physical education. These courses are usually open to students who have completed two years of college work. The professional courses extend over two years and lead to the A.B. or B.S. degree.

In addition to a good general education and professional training, a medical education is considered essential for directors of physical education in colleges, secondary schools, and the public school systems of large cities. The character and personality of the teacher or director are even more important than his education and professional training. He comes in closer contact with a larger number of students than any other school or college officer. He advises students in matters of exercise and hygienic habits. He influences the ethical and moral standards of the students in games and athletic contests. Only men and women of high ideals and deep human sympathy are qualified to assume the responsibilities of directing the physical education of school and college students. G. L. M.

Other aspects of the subject are treated in greater detail under **ATHLETICS**, **EDUCATIONAL**, and the various articles on **HYGIENE**. See also the articles on the various educational games and sports.

PHYSICS.—**Historical Development.**—Physics has been a subject of study in universities ever since their rise in the thirteenth century. Before 1600, however, the official text was the *Physics* of Aristotle, and work in the classes consisted mainly of scholastic disputations on the contents of that work.

During the two centuries (1450–1650) in

which the experimental method of investigation was slowly winning recognition, the nature of the university study of physics gradually changed. The magnitude of this change may be measured by comparing the physics of Aristotle with that of Galileo (*q.v.*). The former is static, seeks final causes, and finds them by classifying phenomena by genera and species, using in this classification not the whole phenomena with its progressive changes, but some one of its static aspects which has been arbitrarily selected as expressing the nature of things. For Aristotle the stone falls because it belongs to the class of objects whose natural condition is one of rest on the earth. The physics of Galileo makes no effort to study final causes, but merely recognizes that the longer the stone falls the faster it moves; and seeks by measurement to determine whether there is any constant relationship between the time of fall and the velocity acquired. This method is dynamic, since it takes account of the constant changes of phenomena and enables us to control and to predict them.

Because modern physics consists of two parts, namely, (1) mathematical discussion based on (2) observation and measurement, these two have of necessity developed side by side in the growth of the science. They have not, however, always been equally emphasized. In the early stages of growth the experimental side has been more prominent; while in the later stages the mathematical analysis has assumed the more prominent position. Thus in static electricity, Gilbert (1600), Gray (1730), Von Kliest (1745), Franklin (1747)—all observers and experimenters—preceded Cavendish (1773) and Coulomb (1785), who put the science on a mathematical basis. In current electricity, Galvani (1780) and Volta (1800) discovered how to make electricity and sought to find out what it would do before Ohm's law (1827) and the Wheatstone Bridge (1843) ushered in the quantitative treatment. Galileo made thermometers (1593), Watt patented his steam engine (1769), and Rumford (1798), Mayer, and Joule (1842) published their celebrated observations before Kelvin (1848), Clausius (1850), and Rankine (1850) traced the mathematical consequences. The observations and measurements of Oersted (1819) preceded the mathematical treatment of electromagnetism by Ampère (1823); and Faraday, the keen observer (1831), preceded Maxwell (1873), the mathematician.

As in the growth of the science itself, so in the teaching of physics in the universities, the emphasis has fluctuated between the mathematical and the experimental aspects. At the time of Newton and for some time thereafter, the mathematical treatment was most prominent. Mersenne's *Opera* (1644), Barrow's *Lectiones Opticarum* (1669), Keil's *Introductio in veram Physicam* (1739), and New-

ton's *Principia* itself are evidence of this. For there was at that time no chance for students to work in laboratories, and even class experiments were practically unknown.

During the latter half of the eighteenth century demonstration lectures at the French Academy became very popular in Paris, and, as is well known, the popular demonstration lectures of Sir Humphry Davy at the Royal Institution in London (*q.v.*) were the inspiration of Faraday (*q.v.*) and started him on his great career. Thus while experimental work necessarily precedes mathematical discussion in the early growth of the science, it seems to have been introduced into teaching because of a popular demand for it.

In Universities and Colleges.—In the university teaching, the emphasis remained on the observational and experimental side from the end of the eighteenth century nearly to the end of the nineteenth century (1890), as is shown by the common use of such books as those of Ganot and Deschanel as texts,—books in the early editions of which there is practically no mathematical work. Since 1890 mathematical work has been rapidly introduced into the teaching. This was a necessary result of the introduction into the courses of individual laboratory work by the students, and of the development of the spirit of research at universities. At present the emphasis, both in the laboratory work and in the theoretical discussions, is very decidedly on the mathematical side. No one can advance beyond the first year of college work in physics unless he has mastered the calculus. In many of the current courses in mechanics, thermodynamics, and optics it is often hard to realize that there ever was an observational and experimental side.

In America the first laboratory teaching of physics to college students was done by E. C. Pickering at the Massachusetts Institute of Technology in 1869. Since that time it has been gradually introduced into all college courses. These courses have also been expanded enormously, owing to the very rapid growth of the science itself. The result of this has been that students who wish to become specialists in physics now have to pass through four or five years of formal training in the technique of laboratory manipulation before they are admitted to original research. The great physicists of to-day were submitted to no such formal training. Whether the present formal system will produce greater scientists than did the rather informal training of the past, remains to be seen.

The changes that have taken place during the last fifty years in the methods of teaching physics in colleges and universities are the necessary accompaniment of the development just presented. For college work the standard texts at the beginning of this period were books like those of Arnot, Ganot, and Des-

channel. These are largely descriptive of phenomena and processes. At present the college texts, like those of Hastings and Beach, Carhart, and Watson, bristle with algebraic symbols and geometrical diagrams. In the older books phenomena usually preceded explanation, while at present definitions, axioms, and laws generally come first, with phenomena dragged in reluctantly at the end in the rôle of applications. Then men were engaged in solving the problems of nature, and students were interested in learning about it; now the student must first learn the man-made definitions and laws and then be shown that nature observes them. The most recent texts show a marked tendency to treat phenomena before laws, and to justify definitions by facts before stating them.

The philosophy of physics has changed much in the past century, but the teaching of it has been slow to follow. In the early part of the past century matter and motion were the controlling ideas; hence all courses began with "properties of matter" and discussions of motion. This is still the customary order, although the doctrine of energy is now the central idea in physics. Physicists have, during this last century, known that laws are but statements of constant relations among measured quantities, and that these laws are true only in so far as further measurements verify them. The majority of college students seem, however, still to get the impression that the laws of physics are true in the absolute sense,—that they express truths that are absolutely true beyond and outside of human experience. This fallacy persists among the students because the current emphasis on mathematical treatment gives to the subject an air of finality which is not properly its own.

In the European universities physics is now taught mainly by demonstration lectures. The type of lectures given is well shown in books like Kundt's *Vorlesungen über Experimentalphysik*, or Pellat's *Cours de Physique*. It does not differ materially from that given in American colleges in their first courses in physics. The time devoted to the course is usually one hour daily for two semesters.

Laboratory work is required only of those who are specializing in physics, medicine, or engineering. The laboratory course or *practicum* for these specialists usually takes two three-hour periods a week for two semesters. The grade of work done is well set forth in the well known manual of Kohlrausch. After completing these one-year lecture and laboratory courses, the student of physics is at once admitted to research work.

In Secondary Schools.—*The United States.*—In the secondary schools of America physics, under the name of natural philosophy, was one of the subjects included in the course of study from the very beginning. Since both

the academies and the public high schools were founded to meet a public need for an education of a more practical kind than that given by the colleges, natural philosophy was taught in them for the value of its information. The people were living in the beginnings of the age of steam and machinery, and they were eager to know something about physics. The early books and courses, therefore, contained no mathematics and much discussion of everyday phenomena and experience.

The early work from 1780 down to 1825 usually consisted in the study of and recitation from a text. In 1827 the city of Boston equipped its schools with some "philosophical apparatus" for experiments by the teacher or by teacher and class together. Laboratory work by the pupils was practically unknown until after 1865. In 1880 the United States Bureau of Education reported but four schools that were giving a full year of physics with laboratory work by the pupils; 53 that were giving experiments by the teacher, and 113 that were giving mere textbook instruction.

In 1872 physics came on the list of subjects accepted for admission to Harvard College, but no laboratory work was required. Arnett was mentioned as the book defining the requirement. The Harvard *Descriptive List* of laboratory experiments required for entrance credit in physics at Harvard appeared in 1887. The influence of this list was strengthened by the report of the Committee of Ten (1895), and by that of the Committee on College Entrance Requirements (1899) of the National Education Association. Following the adoption of this latter report, several apparatus companies put on the market relatively inexpensive sets of apparatus with which all the experiments called for by the report might be made. As a result of all this, the introduction of laboratory work into high school physics has continually progressed until such work is now given in practically every school where physics is taught at all.

While this development of laboratory instruction in physics was taking place, the methods of treating the subject changed rapidly. In 1882 Gage issued his book which bore the motto, "Read Nature in the Language of Experiment." This book is typical of the work done at that time. In the introduction to the Harvard *Descriptive List* (1887) it is stated that the experiments therein described were selected with a view to their having the greatest practical utility in the thought and actions of educated men. In the report of the Committee on College Entrance Requirements (1899) the same set of exercises is said to be designed to give the pupil a "comprehensive and connected view of the facts and laws of elementary physics." Thus it was during this period that "utility to men" was eclipsed by "the logical development of the laws of physics."

This general change in the point of view is evident from a study of the changes that have taken place in the content of the texts intended for school use. The descriptions of machines, daily experiences, and familiar processes, which were plentiful in the days of Natural Philosophy, now give place to more quantitative material, like Newton's laws of motion, the absolute system of units, and instruments for accurate measurement. The 1882 edition of Gage makes no mention of the dyne and the erg as units of force and work. In the edition of 1888 these units are introduced in fine print. In the older books we find many statements like this: A cannon ball that weighs 100 pounds and is moving with a velocity of 100 feet per second has a momentum of $10 \times 100 = 1000$. No units of momentum are specified. This sort of vagueness as to units has largely disappeared, though there are still books which say that the acceleration of gravity is 980 centimeters.

The increasing recognition of the importance of quantitative work in physics has been a mark of real progress. It was, however, carried too far, with the result that in most schools a pupil was introduced into physics through micrometer calipers and the absolute system units. It was the logical method to proceed from the simple to the complex, and what simpler beginning could be found than the gram mass, the centimeter, and the second. Under the desire for logical rigor, the subject matter was organized about the system of absolute units and the effort made to teach physics in this way.

This eclipse of the needs of youth by the science of physics was coordinate with and dependent upon the similar changes that took place in the college world, as described above. While Ganot gave way in the colleges to the *University Physics* of Carhart and the like, Gage yielded in the high schools to texts claiming logical order, mathematical treatment, and up-to-dateness as their chief virtue. The inevitable result has followed. Physics is generally regarded by the high school pupils as a subject to be avoided if possible. In 1900 most of the colleges specified physics as a subject that must be presented for college entrance. Now few, if any, make this a specified subject. It was dropped from the list of specified subjects largely because the number of students who were conditioned in physics at entrance to college became large, owing to a decrease in the number of students who took it in the high schools.

Present Movement.—During the past ten years a decided reaction has been developing against the so-called logical methods of treating physics in high schools. This reaction took an organized form in the National Commission on the Teaching of Physics (1906), which was appointed by the cooperative action of a number of associations of science

teachers. The work of this commission culminated in the definition of the unit in physics adopted by the North Central Association of Colleges and Secondary Schools in 1907. This definition is noteworthy for its brevity and for the complete absence from it of all demand for abstract mathematical work. In 1909 the College Entrance Examination Board adopted a new definition of its requirement in physics. This definition was framed by a committee of six secondary school teachers without assistance from the colleges, and warns teachers against the disguise of unfamiliar units.

Physics teachers are now working, through several committees, on the problem of bringing their work close to the pupils by using in their classes problems and apparatus such as the pupils meet in their daily lives. This is a complete reversal of the methods of a few years back. Then it was considered necessary to present definitions and general principles first, and to bring in the home experiences and familiar machines only by way of illustration or application. Now the pupil begins by a study of some particular familiar thing, — a water motor, a hoisting crane, a gas stove, an electric bell, — and is led thence to the formulation of the principles involved.

Europe.—In the secondary schools of France and Germany physics is taught in small doses extending over a long period. The pupils in the scientific courses carry the subject during the last five years of their work, — two hours a week for three years, and then three hours a week for two years. This is equivalent to a little more than two units in the American system, but its extension over five years has obvious advantages in the way of allowing the difficult concepts of physics to develop slowly in the pupils' minds. Outlines of the work done in these five years are given for Germany in Gutzmer, *Die Tätigkeit der Unterrichtskommission der Gesellschaft deutscher Naturforscher und Aerzte* (Teubner, 1907); and for France in the *Plan d'Etudes et Programmes d'Enseignement* (Paris, Hachette). The total ground covered in these courses is a little more extended, but not very different from that which many American high schools attempt to cover in the time of one unit.

It has been noted that students abroad enter research after the equivalent of three units of training in physics. This again raises the question whether the four or five years of preliminary training required in America is a benefit to the students or not.

The foreign secondary schools are considerably behind the schools of the United States in the development of individual laboratory work in physics. It is only during the last eight years that serious attention has been given to this matter. Much progress has been made in this short period, and at present

laboratory work by the pupils is being rapidly introduced everywhere. The kind of work done is practically the same as that done in America under the standardized system of the national physics course. A reaction against this formal and logical method is also well under way in Germany. From many sides the demand for more practical and vital work is heard. The term *Arbeitsunterricht* has there come into prominence of late.

Elementary Schools.—In the elementary schools physics has received relatively little attention. During the early years of their development (1820-1870) some little work of a descriptive character was attempted; but from 1870 to 1900 very little effort was made to teach physics in any form in the grades. In 1895 the Committee of Fifteen on Elementary Education recommended to the National Education Association that *one full hour a week* be devoted to science during the whole eight years of the course, and that in the seventh and eighth grades the time be devoted to physics and chemistry. This recommendation, as far as physics was concerned, was not followed eagerly by the schools as a whole. The nature study movement was just beginning to develop, and its emphasis was on physical geography and the biological sciences.

In some few places, notably in New York City, a serious attempt has been made to develop a course in physical science in the seventh and eighth grades. In that city in 1903 a new plan of nature study was adopted. A syllabus was issued according to which the work of the seventh and eighth grades was to be a complete course in elementary physics. The aim of this course is not only to acquaint the pupil with the fundamental laws and principles of physics, but also to train him in habits of close observation, accurate thinking, and correct expression; in short, the emphasis is on physics as a well-organized mass of knowledge and on mental discipline, rather than on the need of the child. This course occupies two forty-minute periods a week. Laboratory work has been introduced, in which the pupil does set experiments and writes them up in his notebook. The method of presentation recommended is: (1) presentation or demonstration by the teacher; (2) individual laboratory work by the pupils; (3) recitations on the demonstration and the laboratory work. The kind of laboratory experiments recommended are: (1) those that verify laws demonstrated by the teacher; (2) those that are wholly or largely quantitative in character; (3) those that will impart a certain degree of mechanical skill. It is claimed that this work also fosters in the pupils the scientific habit of mind. Notwithstanding this effort in New York City and elsewhere, the teaching of physical science in grade schools has not made much progress in the country at large.

Another type of work in physical science in the seventh and eighth grades has recently been developed in experimental schools like that of the Teachers College in New York and that of the College of Education of the University of Chicago. A practical problem is presented to the class, such as: Is it cheaper to make a still and distill water on a gas stove than it is to buy distilled water from the druggist? The pupils construct stills, measure the gas consumed in distilling a measured quantity of water, and compute the cost per gallon. This type of work creates a lively interest among the pupils. It makes no pretense of logical order or rigorous treatment. Its chief aim is to teach the children to analyze familiar phenomena and to solve by the method of science simple and real problems in physics which yet lie well within the range of their daily experiences. The child and his needs are the center of the course rather than the organized science of physics. Courses of this kind have not yet been organized with sufficient definiteness to make them available for use in city school systems; nor has an adequate supply of teachers competent to carry on work of this kind successfully been forthcoming as yet.

The general lack of work in the physical sciences in the grades has led recently to a demand for a course in "general science" in the first year of the high schools. Physiography is usually given in the first year in the secondary schools, and many claim that it serves the purpose of opening the eyes of the pupils to the importance and the interest of further scientific study. In many cases, however, physiography has become too much specialized to serve the purpose of a general introduction to science. Courses in general science have, therefore, been organized in numerous places, which usually consist of a series of topics and problems such as: How are grease spots most easily removed from clothes? What are the conditions for making good pictures with a pinhole camera? How do spectacles improve eyesight? Which kind of gas burner is most economical? What are the traps on the waste pipes of sinks for? How is water purified? Numerous first-year courses of this general type have been developed in secondary schools. In most of the places where the experiment has been tried, it is pronounced a great success in increasing the general interest of the pupils in science and in swelling the numbers of those who take the later more advanced courses in physics. The courses that have been arranged differ widely as to content. There is as yet no general agreement either as to content or as to the organization of it. The entire movement is still in the experimental stage, but it shows very clearly an effort to develop a type of science teaching which shall make the needs of the pupils rather than

PHYSIOGNOMY

logical organization the controlling element in the work.

The justification of the new methods of treating physics is readily found in the history of physics, in the recent analysis by the psychologists of the doctrine of formal discipline, in the present demands of the people for the development of social and industrial efficiency in education, and in the recent developments of the philosophy of science.

PHYSIOGNOMY.—See LAVATER, J. K.

PHYSIOGRAPHY.—See GEOLOGY; GEOGRAPHY.

PHYSIOLOGICAL AGE.—A term which refers to stages of development and is, therefore, to be distinguished from chronological age, which refers to the calendar of years and months. The succession of the stages of development, maturity, and senescence form the calendar to which any living individual may be referred for designation as to physiological age. It is held that the statement of the stage of development is more fully descriptive of the individual than is a statement of years and months of age, alone, for the former gives information as to structural condition, physical and mental abilities, characteristic of the stage, while the latter refers only to

PHYSIOLOGICAL AGE

length of life. Owing to different rates of development, chronological age gives imperfect information as to actual mental or physical status.

The physiological calendar of developmental stages is a series of anatomical, physiological, and mental signs which serve as data for reference. This has given rise to the additional terms "anatomical" and "psychological" age, depending upon the nature of the sign noted for reference. Of the former, Rotch has presented a series of developmental epochs based upon the appearance of the ossification centers of the bones of the wrist; of the latter Binet and his followers have presented a series of tests of mental abilities. These signs vary in significance as to the number and closeness of their correlations with other important features of development. Of the least importance at present are the anatomical signs of earlier tooth appearance and the development of the bones of the wrist, for with them little correlation with other features of maturation has been determined. Of greater importance are the signs of puberty and menopause with which many significant qualities are closely correlated. At puberty, of which pubic pubescence is the sign, the voice changes, a growth acceleration begins, physical proportions change, many mental abilities wax and wane, and the whole social attitude changes.

Strength of grip, right hand. Stage of pubescence of a group of 662 high school boys between 14.6 and 15 years of age.

Since puberty may occur at any age between six and twenty, and commonly from eleven to sixteen, the mere statement of a chronological age, as, for instance, thirteen years, gives no information as to whether or not these

most significant changes have or have not occurred; while the statement of physiological stage with reference to pubescence will more accurately describe the individual.

We divide children from eleven to sixteen into three classes—prepubescents, pubescents, and postpubescents, according to the absence, first appearance, and evident presence of pubic hair. The preceding table illustrates the fact that postpubescents are much stronger than prepubescents. Similar investigations determine that they are proportionately taller and heavier, and that their success in school and their growth rates are also very different.

Owing to the fact that this thesis is new, the physiological calendar is incomplete, and the significance of each of its data of reference has not been fully stated. The importance of basing education upon the observed succession of developmental stages, instead of the chronological basis, has become apparent, and efforts have been made to bring about the change. The recognition of the fact that the neuromuscular abilities of the postpubescent boy are superior to those of the prepubescent boy has led to a classification for purposes of athletic competition upon the basis of weight, which is closely correlated with pubescence, and in many cases the division is made upon the actual observation of pubescence.

The following table, taken mainly from Boas, exhibits the anatomic and physiological development calendar as it is at present formulated. The corresponding psychological calendar is at present unformulated.

OBJECTIVE SIGN	AVERAGE DATE	VARIABILITY (SIGMA)

PHYSIOLOGICAL PSYCHOLOGY.—See PSYCHOLOGY.

PHYSIOLOGY.—That phase of biology which treats of the functions or life activities

of animals and plants. General physiology deals with fundamental processes which are common to all organisms. The terms animal physiology and plant or vegetable physiology are commonly applied to the subdivisions which treat of life processes in animals or plants, respectively. (See BIOLOGY; BOTANY.) Human physiology in the strict sense is the science of human functions; and it is chiefly a division of animal physiology, for the comparative study of animal life has contributed numerous facts and principles applicable to the human aspect of the science. Human physiology is popularly more or less confused with hygiene, probably because personal hygiene is largely an application of physiology supplemented by some applied bacteriology. Public hygiene, on the other hand, depends primarily upon applied chemistry and bacteriology in the public control of conditions which affect the health of communities. Having now defined the field of physiology as a subsience of biology, an outline of its various relations to education will be more intelligible.

In Universities and Medical Schools.—Only in advanced courses in some universities and medical schools is human physiology presented as a separate branch of science, while the necessary facts of anatomy and histology are taught in prerequisite courses. More commonly, college courses and large textbooks which are designated "physiology" contain a large admixture of anatomy, chiefly microscopic, but sometimes gross also. Moreover, in some colleges there are no announced courses of physiology, but the human side of physiology is presented as a culmination of general biology.

In Schools.—With reference to schools of secondary and elementary grade the term "physiology" has been very loosely used, especially in America, and has been applied to various courses of study of the human body, some of them based on textbooks with less than 10 per cent of their pages devoted to physiological topics. In defense of the use of the word "physiology" for such elementary studies of the human body, it has been urged that the whole study revolves around functions; and the same kind of argument might also justify the more recent use of "hygiene," for such studies as are of value chiefly with reference to health. Numerous authors of elementary textbooks have avoided such unwarranted use of the term physiology by adopting such titles as "human anatomy, physiology, and hygiene," "human mechanism," and "human body and health."

Instruction concerning the human body, and especially aiming at health, is in many states required by law in the six or seven years between the second grade of the primary school and the second year of high school. (See TEMPERANCE, INSTRUCTION IN.) In most cases the laws do not specifically require anat-

omy and physiology, but obviously some fundamental facts in these lines are necessary as a scientific basis for teaching hygiene. The general tendency of recent years has been to reduce the amount of human anatomy and physiology in elementary courses for public schools, in order to make way for more hygiene, particularly the problem of germ diseases. There is excellent authority for teaching in elementary schools only as much physiology as is needed for application in hygiene and only as many facts of anatomy as are useful in physiology.

The most recent movement affecting public school "physiology" is the attempt to make it an integral part of nature study for elementary grades and of general biology, or sometimes zoology, courses of high schools. The elementary school adjustment to nature study has been studied in only a few schools, although advocated by many prominent science teachers. (See NATURE STUDY.) The inclusion of high school physiology and hygiene in biology courses is very common in many high schools, and is officially recognized in courses of study in some states, notably New York. Practically all prominent teachers who have tried presenting human physiology and hygiene in connection with high school biology favor the plan because so much of the usual studies of animals and plants helps to interpret human structure and functions. In fact, the only possibility of teaching physiology and hygiene on the laboratory basis is by making use of illustrative materials selected from the fields of botany and zoology.

In some systems of elementary schools and in a few high schools the teaching concerning the human body has been designated hygiene and placed in the charge of teachers of physical training. The experiment has been far from successful, chiefly because hygiene is best taught by classroom and laboratory methods and with illustrative materials which are quite foreign to the standard physical training. Moreover, there are relatively few possible correlations between hygiene and physical training outside of breathing and muscular activity. Probably most useful of all elementary hygiene is that relating to food and germs, and these certainly have no relation to physical training. On the other hand, they are natural applications of biological nature study and high school biology. M. A. B.

For more detailed presentation of the educational status of the entire subject, see HYGIENE, PERSONAL; HYGIENE, SCHOOL; HYGIENE, TEACHING OF; PHYSICAL EDUCATION; TEMPERANCE, INSTRUCTION IN; also NATURE STUDY; MEDICAL INSPECTION; SANITARY SCIENCE; SEX HYGIENE.

PIARISTS.—A teaching order established by Joseph Calasanctius (1556-1648), a Spanish priest, who was born near Petralta in Arragon and after studying at Lerida, Valencia, and Alcalá proceeded to Rome. Here he was struck by the lack of educational opportunities for the poor, and with the aid of two priests opened a free school in 1597. The work grew rapidly and further assistance was obtained. In 1606 there were 900 pupils under instruction; in 1613 there were 1200. In 1621 Pope Gregory XV permitted the establishment of a teaching congregation—*Congregatio Clericorum regularium pauperum Matris Dei Scholarum piarum*, known also as the *Patres piarum Scholarum*. After much opposition and internal troubles the order was once more confirmed by Pope Clement IX. The members wore a habit much like that of the Jesuits, whose general organization was also copied in the main. The Piarists undertook primary education—*ad majus pietatis incrementum*. From Rome they were soon invited to other parts of Italy and then Spain. In 1631 they took up work in Moravia; in 1640 in Bohemia; in 1642 in Poland; and after the Thirty Years' War in Austria. In the eighteenth century and in the early part of the nineteenth the Piarists were particularly influential in Austria and Hungary, especially after the expulsion of the Jesuits. Besides elementary education they had been allowed by Pope Clement XII in 1731 to give higher education, and they established many higher schools. From 1804 to 1849 they had charge of the *Academia Theresiana* in Vienna. Throughout the latter half of the last century, however, there has been a decline in the activity of the Piarists in Austria. Their chief centers are now in Italy, Spain, and America. While they followed a scheme very similar to the Ratio of the Jesuits, they did not adhere to it so rigidly; nor were they so narrowly classical as the Jesuits. They divided the school work into nine classes: reading, writing, ciphering, *schola parva* or *rudimentorum*, *schola principiorum*, *grammatica syntaxis humanitas* or *poesis*, and *retorica*. To avoid fatigue school work was never continued beyond periods of three days. The work of the congregation is organized in provinces. At the head stands a *Præpositus generalis* with four assistants and a *Procurator generalis*, all in Rome. The chief authority in each province is the *Dicasterium provinciale*; the head of a college is the *Rector*; of a settlement, the *Superior*. A general chapter takes place at

Rome every six years for the discussion of the larger questions of administration.

PIERPONT, JOHN (1785-1866).— Text-book author; graduated at Yale College in 1804. For five years he was teacher in the academy at Bethlehem, Conn., and private tutor in South Carolina. He studied law at Litchfield, Conn., and practiced a few years at Newburyport, Mass. He then took the course in theology at the Cambridge Divinity School and devoted the remainder of his life to the ministry. He was the author of a series of school readers, including the well-known *American Class Book* (1831). W. S. M.

PIERSON, ABRAHAM (1645-1707).— First president of Yale College; graduated from Harvard College in 1668. He was ordained to the ministry, and was assistant pastor (under his father) at Newark, N.J., and pastor at Killingsworth, Conn. He was the first rector of Yale College (1701-1707). He published an Indian catechism and a work on natural philosophy, which was studied in the college for many years. "He was an excellent scholar, a great divine, a faithful preacher, and wise and judicious in all his conduct." W. S. M.

See YALE UNIVERSITY.

PIETISM.— A movement which occurred within the Lutheran Church in the seventeenth century, stimulated by the opposition to the formalism and intolerance in the dogma and practice of the church. The result of the Thirty Years' War had been to establish a number of "little popes," each with his own official clergy to protect an intolerant creed. Theological quibbling on questions of doctrine, a cold, logical, and intellectual religion, had sprung up, and close adherence in forms was demanded. Against this condition came a movement for practical Christianity, pious conduct, and faith; the heart rather than the intellect was the seat of religious beliefs. Philip Jacob Spener (1625-1705) is generally regarded as the leader in the movement. He had, how-

ever, several predecessors whose work tended in the same direction. Among these may be mentioned Johann Arndt, Johann Valentin Andreas (*q.v.*), and Balthasar Schuppis.

Pietism was a demand for the expression of piety and devotion in individual action; conduct was to be inspired by inner light, deep reverence, and true conception of religion. Hence there followed naturally love of God and love of man; the spiritual and the social went together. To pietism in no small measure was due the humanitarian and philanthropic activity of the eighteenth century.

Strong as the influence of pietism was in religion, it was even more powerful in education. Both Spener and Francke held that the faults of the age were due to bad upbringing of children in home and school, and to poor teaching. They recognized the evil of allowing the memory to run ahead of intelligent comprehension, and further they saw the defects of an education which stressed verbalism and neglected the real and practical. As in religion the chief cause of prevailing conditions was a divorce between doctrine and practice, so the remedy in education was to be found in a combination of the word and the thing. But the leaders of the movement also realized that the benefits of education were confined to only a few. The lower classes, the poor and destitute, were almost entirely neglected. Accepting the theory of the total depravity of children, the pietists were compelled logically to accept and provide education as a discipline for the conduct of life. The result of the two views on the function of education was to relate knowledge to the needs of life, a life directed to higher ends—love of God and human sympathy. Thus a change in the curriculum in the direction of the modern and practical was no longer impossible. From the social-philanthropic aspect a new movement began for the provision of schools for orphans. As Spener was the leading influence on the religious side, so Francke (*q.v.*) was the moving spirit on the educational. All the implications which flowed from the pietistic movement were realized in the great *Stiftungen* of Francke at Halle (1695). Throughout Germany this influence was felt almost immediately, and led to the establishment of schools for the poor and to the foundation of orphanages. Connected with these went the training of teachers, also in imitation of Francke's system. At Halle, too, was established the first "real" school by Semler in 1706, based on the principle *non scholæ sed vite discendum*. Although this school did not meet with success, it was the prototype of the "real" school established by J. J. Hecker in Berlin in 1747 and so of the "real" schools of Germany. Through Hecker the stamp of pietism was also laid upon Prussian elementary education, for he was in large part responsible for the *Generallandschulreglement*

of 1763. But the influence of pietism which thus emphasized the value of the vernacular did not end with the elementary and secondary schools. Through Spenser, Francke, and Thomasius (*q.v.*), after the failure of the two latter to introduce the use of the vernacular at the University of Leipzig, the University of Halle (*q.v.*), probably the first modern university, was established.

As a religious movement pietism, like other similar movements, at times degenerated into fanaticism, and while it had originated to vindicate human values, it ended in decrying every thought and action in the slightest degree worldly. In education, however, it laid the foundations of modern ideas: an increased importance was attached to the vernacular; the "real" studies were encouraged; practical needs were not disregarded; better methods replaced the old emphasis on discipline and memory; schools were provided for the lower classes; "real" schools were introduced; and teachers began to be trained. Nor were these influences confined to Germany. The Moravians (*q.v.*), a direct offshoot of the pietist movement, established schools as soon as they were organized. In England the charity school movement (see CHARITY SCHOOLS) was due to similar influences; in England and America the Quakers were an equally important factor in the development of education (see BRITISH AND FOREIGN SCHOOL SOCIETY; FRIENDS, EDUCATION OF SOCIETY OF; LANCASTER, JOSEPH, *etc.*); while similar movements, almost contemporaneous with pietism, led to educational reforms in France. (See CHRISTIAN BROTHERS; LA SALLE, ST. JOHN BAPTIST DE; PORT ROYALISTS.)

PIKE, NICHOLAS (1743-1819).— Author of one of the earliest popular American arithmetics; was graduated at Harvard College in 1766. He taught for several years and in 1788 published his *New and Complete System of Arithmetic*, which for nearly half a century was in general use in America.

W. S. M.

PILLANS, JAMES (1778-1864).— Scotch educator, born and educated in Edinburgh. He graduated M.A. at the Edinburgh University in 1801; for several years he was a private tutor at Eton, and from 1810 to 1820 he was Rector of the Edinburgh High School. As Rector he met with considerable success, increased the number of pupils, and introduced the monitorial system for the first time in a secondary school. He was especially interested in the teaching of Latin, Greek, and ancient geography. His experiment at the high school attracted much attention, particularly in France, where he was made a member of the *Société pour l'Enseignement élémentaire*. In 1820 he was appointed to the chair of Humanities and Laws, a position held by him until 1863. Professor Pillans had an intimate acquaintance with all types of school in England, Scotland, Prussia, France, Switzerland, and Ireland. In 1856 he published a volume containing most of his writings on education under the title *Contributions to the Cause of Education*. The speeches and essays are characterized by breadth of view and are the fruit of wide educational experience. Professor Pillans was a warm supporter of the professional education of teachers and of the improvement of their social status. Professional education he did not consider to lie in higher education or a training in devices and methods, but in principles and psychological foundations of education. He urged the establishment of chairs of education in Scotland as early as 1828, and continued advocating these to the end of his career.

PISA, UNIVERSITY OF.— See ITALY, EDUCATION IN.

PITCH.— The quality of a tone. The tonal range of the normal ear extends from the lowest audible tone, about twelve vibrations per second, to the highest audible tone, about fifty thousand vibrations per second. The lower limit is usually determined by means of large tuning forks, and the upper limit by means of a 'Galton whistle. The range is greatest in early youth. The upper limit is lowered with age to such an extent that at sixty a person may not have more than about two thirds of the range he had at sixteen. Sometimes gaps occur within the tonal range, i.e. a person is incapable of hearing tones of a certain pitch, although he may hear both higher and lower. This is analogous to color blindness. C. E. S.

See EAR; SOUND.

PITTSBURGH, UNIVERSITY OF, PITTSBURGH, PA.— The oldest existing institution of learning west of the Alleghanies. It was

first chartered on February 28, 1787, as Pittsburgh Academy; later, in 1819, as the Western University of Pennsylvania. In 1908 the title was changed to University of Pittsburgh. In 1822 the first college faculty was installed. By state appropriation the first college building was erected. Fires in 1845 and 1849 destroyed the buildings. In 1866 the University acquired the Allegheny Observatory, and new buildings upon the observatory site in Allegheny were completed in 1890. In 1908 a new site was chosen, consisting of forty-three acres in the Oakland district. By 1912 five buildings had been completed on this site. The Chancellors of the University, at first called principals, have been as follows: Robert Bruce, 1819-1843; Heman Dyer, 1843-1849; D. H. Riddle, 1849-1855; John F. McLaren, 1855-1858; George Woods, 1858-1880; Henry M. MacCracken, 1881-1884; Milton B. Goff, 1884-1890; William Jacob Holland, 1890-1900; John Alfred Brashear, 1901-1904; Samuel Black McCormick, 1904-. The purpose of the second charter, to create in western Pennsylvania a university similar to the University of Pennsylvania in the east, was partially carried out from 1840 onward, in the establishment of courses in law, in advanced English, in engineering, in astronomy, and in medicine. In 1892, under the chancellorship of Dr. Holland, this purpose was fully realized in the establishment of schools of medicine, law, dentistry, pharmacy, and mines. All these are now located on the university site, with the exception of the observatory (situated permanently in River-view Park), and the schools of law and pharmacy, which will shortly be transferred.

The University of Pittsburgh now consists of eleven schools, as follows: college, engineering, astronomy, graduate, mining, economics, education, medicine, law, dentistry, and pharmacy. It is managed by a self-perpetuating Board of Trustees, consisting of thirty members, together with the Chancellor and the mayor of the city. The entrance requirements are the usual fifteen units. The school of medicine requires two years of college work. Entrance to the law school is determined by the rigorous requirements in that profession in Pennsylvania, the student body for the most part holding bachelor's degrees. In the year 1911-1912 the faculty of the University consisted of 271 members. The students numbered 2258, distributed as follows: graduate school, 68; college, 345; engineering, 176; mines, 46; economics, 425; education, 502; law, 170; medicine, 190; pharmacy, 200; dentistry, 165. The University has (April 1, 1912) assets amounting to more than two million dollars. Its support comes from private endowments, individual gifts, and biennial appropriations from the state.

The location of the University in the world's

greatest industrial center gives prominence to certain of its departments. Among these are medicine, with the splendid hospital facilities; engineering, with its unrivaled laboratories in the mills and manufactories, which make possible the new coöperative system whereby engineering students gain practical experience while engaged in study; research work in industrial chemistry, with the system of industrial fellowships, which are rapidly multiplying; economics, sociology, etc., courses in which are extending with rapidity and effectiveness; education, with its plans for coöperating with the public school system in western Pennsylvania. S. B. M.

PLACE, FRANCIS (1771-1854).—Publicist and educationist. He was born in a "sponging house," or private debtor's prison, in Vinegar Yard near Drury Lane, London, his father, Simon Place, being a bailiff to the Marshalsea Court. Afterwards the father took a tavern, and Francis was brought up with arab-like street life out of school, and actually taught other pupils in school. From 1784 to 1789 he was apprenticed to a leather-breeches worker. In 1791 he married Elizabeth Chadd, when their joint earnings amounted to seventeen shillings a week. With a period of unemployment in 1793 he became overseer of parish scavengers, but notwithstanding every discouragement he gave himself up to intellectual improvement by borrowing books on loan. By 1796 he had become an agnostic, and took part in publishing Tom Paine's *Age of Reason*. In 1799 he opened a shop as a tailor, determined not to exercise the ordinary tricks of tradesmen. Place came into contact with Joseph Lancaster (*q.v.*), sent a son to one of his schools, and endeavored to make the movement, not only a charitable plan for the children of the poor, but the basis of an organization of a complete system of primary and secondary education, at least for London, and was one of the pioneers in the movement of "Schools for All." One of Place's distinctive suggestions was a system of higher schools in connection with the Lancaster Society, so as to help the middle classes as well as the poor. He was particularly anxious, like Ellis (*q.v.*) later, that systematic courses of morals should be included in the curriculum. Bentham offered a site for such a school, and the proposed curriculum was founded on the *Chrestomathia* of Bentham (*q.v.*). James Mill joined Place in drawing up the proposed plan in 1815, but the scheme finally failed in 1820. In 1823 Place was instrumental in founding a London Mechanics Institute (*q.v.*), which was further developed by Dr. Birkbeck (*q.v.*), and which with day classes attached has become one of the most important recognized "schools" of the University of London. Place advocated, at the beginning of the nineteenth cen-

tury, schools for all, buildings to be erected at the cost of public authorities, compulsory rates for education, and good teaching on a strictly non-sectarian basis. He was a leader against the laws forbidding combinations of workmen, and was an important source of information on social questions for the first half of the nineteenth century, having left seventy-one volumes of manuscript and materials, largely autographical, now placed in the British Museum Library. F. W.

WALLAS, GRAHAM. *Life of Francis Place.* (London, 1908.)

PLAMANN, JOHANN ERNST (1771–1834).—German educator, born in Berlin and there educated at the Royal Real School and the Joachimsthal Gymnasium. After studying theology and pedagogy at Halle, he was private tutor for a time, until he became so full of enthusiasm for Pestalozzi's work that he decided to visit him in Switzerland. He remained at Burgdorf from May to October of 1803 and was in intimate touch with Pestalozzi. On his return he opened a Pestalozzian institute in Berlin with royal authority. The first effort failed, owing to trouble with the school authorities. In 1805 Plamann opened another school on Pestalozzian lines and met with great success. This institute became the center of Pestalozzianism in Prussia. The authorities encouraged young teachers from all parts of Prussia to visit Plamann, and Von Humboldt sent his son to the school, through which he was converted to Pestalozzianism. Among the future educational leaders who received their training through Plamann may be mentioned: Harnisch, Jahn, Kawerau, and Dreist. Plamann visited Pestalozzi a second time in 1812. Plamann was the author of several books on the Pestalozzian system: *Einzig Grundregel der Unterrichtskunst nach Pestalozzi's Methode, angewandt in der Naturgeschichte, Geographie und Sprache* (Some Principles of the Art of Instruction according to Pestalozzi's Method applied to Natural History, Geography, and Language, 1805); *Anordnung des Unterrichts für ein Pestalozzische Knabenschule* (Course of Instruction for a Pestalozzian Schools for Boys, 1806); *Elementarformen, Sprach- und wissenschaftlichen Unterrichtskunst* (Elementary Methods of Instruction in Language and Science, 1906); *Beiträge zur pädagogischen Kritik; zur Verteidigung der Pestalozzischen Methode* (Contributions to Educational Criticism, in Defense of the Pestalozzian Method, 1815).

PLANCHETTE.—See MUSCLE READING; AUTOMATOGRAPH.

PLANS, LESSON.—In order to train teachers to anticipate and prepare for all the essential demands that will be made by the conditions of the classroom and the standards of effective teaching, it is customary to require the preparation of lesson plans by students of the teaching process. At first such plans are usually for a single lesson period; later, they may cover a group of lessons; later still, with more experienced teachers, a scheme of procedure for the work of a month or a term. A common type of lesson plan makes a preliminary statement of aims (for both teacher and pupils), and then in parallel columns suggests the *subject matter* and the *method of procedure* to be utilized in developing the lesson.

The advantage of the lesson plan lies in its usefulness as a device:—(1) in anticipating the situations which are to be used in controlling the experiences of children, (2) in stimulating the teacher to an adequate gathering of the materials which are the basis of instruction, and (3) in defining the teacher's activities so as to avoid discursiveness. Mechanically used, the lesson plan tends to make teaching formal and inflexible. It should be used as a guide (rather than as a fixed plan), elastic enough to be modified to meet the unforeseen situations and spontaneous interests that constantly appear in every classroom. Fullness of detail in such careful advance planning is requisite for beginners in order to clarify the teacher's thinking and to give a basis for advance criticism on the part of the supervisor. More schematic planning covering wider units is more profitable for experienced teachers in service, inasmuch as they have in large degree perfected their scholarly and pedagogical resources, and have attained an easy self-command in the classroom. For trained teachers, a demand for detailed written plans may prove wasteful of time and energy. H. S.

PLANTA, MARTIN (1727–1772).—Swiss educator born, at Sûs in the Grisons and educated by his brother. After studying theology at Zürich, he was tutor for a time in Germany and then (1750) pastor of a German congregation in London. Here he also studied mathematics and physics, to which he contributed several inventions. Returning to Switzerland, he became pastor at Zizers in 1754. In 1761, after consulting the French Minister Ulysse de Salis-Marschlins, the diet of Grisons, and members of the *Société Helvétique*, he with a friend, J. Peter Neseemann, a former pupil

of the Franckesche Stiftungen, opened a school, the *Séminaire* or *Séminar*. This was soon transferred to Haldenstein and met with great success, attracting foreign as well as native pupils. The aim of the school was "first to give a Christian education, and secondly to prepare pupils for the various careers, political, administrative, military, and commercial." The curriculum was broad and included: Latin, French, German, history, geography, law, natural law, practical mathematics, bookkeeping, design, music, and drawing. Mechanical methods were replaced by attention to individuality, appeal to the intelligence, and independence. Ulysse de Salis-Marschlins in a tribute to Planta referred to the following features in the school: "Self-government of the pupils as a stimulus to ambition and preparation for a republican life, the Socratic method, and the religious foundation." The school was organized on the model of the Roman republic. Emphasis was placed upon physical exercise, including gymnastics and excursions. The pupils were encouraged to make collections of minerals, plants, and insects, and were also taught manual work of different kinds. In 1771 the school, having now ninety-six pupils, was once more moved to the castle of Marschlins. About this time, too, Planta designed to open a free school for poor pupils of ability. On Planta's death in 1772, K. Fr. Bahrdt, a disciple of Basedow (q.v.), was given charge of the school, now known as a *Philanthropinum*. But Bahrdt did not have the personality to carry on the school with success, and it was closed in 1776.

PLANUDES.—See MAXIMUS PLANUDES.

PLASTICITY.—Modifiability. That property of living organisms which enables them to adapt their behavior to changes in their environment. The term may also be applied widely to cells of which the organism is composed or even to non-living matter that retains the modifications which result as a consequence of action upon it. The term is generally used, however, in connection with those changes which are clearly adaptive.

Under the condition of rapid changes in environment any animal species which is plastic will have an advantage over those which are not capable of modifying their behavior to suit the new conditions. According to the theory of organic selection the presence of plasticity serves to modify the influence of

natural selection by enabling the animal possessing it to form new habits suitable to the changing environment, which promote the survival of the animal until natural selection has time to secure more fundamental adaptation.

According to this view, therefore, in a species which survives because of its plasticity, each individual will require education in order that it may be brought into harmony with its environment. Man's nervous system is preëminently the most plastic of all animals' by virtue of the comparatively large size of his cerebral hemispheres. Corresponding to this fact we have the lengthened period of infancy, which is the period devoted to the learning of new modes of behavior. Man is, therefore, comparatively much less dependent upon instincts and reflexes than the lower animals and much more dependent on habit, making education a virtual necessity. The human nervous system becomes much less plastic in middle and old age, as shown in the relative difficulty in learning new habits both of thought and action.

PLATEAU.—See HABIT; also LEARNING; PRACTICE CURVE.

PLATO.—The educational influence of Plato is so all-pervasive that it is impossible to give an adequate statement of it, even had the subject not been treated under a variety of other topics. In the general article on GREEK EDUCATION it is the ideas and influence of Plato that are expressed for the most part in the discussion on the THEORY OF GREEK EDUCATION (Vol. III, pp. 153-155). Again, in the article on IDEALISM AND REALISM IN EDUCATION (Vol. III, pp. 371-375) it is chiefly Plato's influence which is discussed. In the article on ETHICS, on LOGIC, on PHILOSOPHY, and especially in PHILOSOPHY OF EDUCATION, it is again Plato's influence which is stressed as fundamental. In the articles on MYSTICISM AND NEOPLATONISM his influence during the late classical and medieval periods is considered. Throughout the entire list of topics relating to the philosophy of education (see ANALYTICAL INDEX in the last volume), Plato's influence is to be noted, especially in such articles as those on KNOWLEDGE, IDEA, LAW, etc. The following article, therefore, is limited to a brief statement of the chief points of Plato's influence on education. The Platonic schools of education, as worked out in an ideal system, are found in their most

systematic form in *The Republic*. As stated above, these accord in general with the most advanced educational theory of the Greek people. In a similar way, Plato's most concrete statement of educational practices, as found in *The Laws*, is in general a transcript of contemporary Greek practices. Both are therefore given in substance in the general article on GREEK EDUCATION.

Higher education in Plato's scheme was almost exclusively mathematical, though we know that he encouraged grown men, like his nephew, Speusippus, and Aristotle, to study other branches of science, such as geology, botany, and zoology. That, however, belongs to the history of scientific research rather than to that of education, and it is clear that Plato insisted upon a preliminary training in mathematics for all his students. The whole scheme is really the development of a single thought, which he owed in great measure to the Pythagoreans. The earlier education was directed to the inculcation through time and tune of an instinct for order and harmony. An ordered and harmonious soul is the first requirement of a good citizen; but, besides that, the Greeks felt that the intervals of the octave had their counterpart on a larger scale in the ordering of the heavenly bodies, and that the great universe itself was tuned like a lyre. The aim of education is, therefore, to put the soul in tune with the world and with God. That is why it is mathematical throughout.

It is becoming more and more clear that Plato's *Laws* had a very great influence in the age which immediately succeeded him. Already in his own lifetime the Academy was recognized as a school of politics, and especially of constitutional law. Many cities applied to it for legislators, and in this way the theories of *The Laws* came to be realized in the codes of actual states. This seems to have been the case with the educational principles contained in the work also. It is generally recognized that, by founding the Academy, Plato became the real author of the university system; it is not always noticed that he was also the inventor of the school as we understand it. At Athens in the classical period there were no schools at all, if we mean by a school a public institution with a regular curriculum. Parents sent their sons to one teacher to learn reading and writing, to another to learn music, and so forth; but all these teachers were private tutors, as it were, and quite independent of one another.

In recent times, much attention has been paid to Plato's theory of education, but this has been almost entirely confined to the discussion of the subject in *The Republic*. As has been said, the guiding principles are to be found there, and they are rather assumed than established in *The Laws*. It is from *The Republic* that we learn his view that education is above all a sort of conversion, a turning of

the eye of the soul to the light. It is also from *The Republic* that we learn the psychological basis of the system. It is not correct to say, as people usually say, that music is the education of the soul and gymnastics that of the body. Rather these are the education of two different "parts" or elements in the soul, and the excess of either produces an ill-balanced and inharmonious character.

It is also from *The Republic* that we get a fuller knowledge of the higher education in its four main branches of arithmetic, geometry, astronomy, and music, which long survived in the medieval *quadrivium*. But, on the whole, what we chiefly owe to Plato is the idea of an organized school with a definite curriculum, and that is derived from *The Laws*.

Platonic Philosophy of Education.—Plato's treatment of education is a closely interwoven fabric of interpretation of the social and moral conditions of his own day, with principles and problems having a perennial import. His most important contributions to a permanent philosophy of education may be enumerated as follows:—

1. The problem of education is an inherent portion of the philosophic question, and conversely education is treated as the social and moral art through which the theoretical results of philosophy shall be made effective in life. (See PHILOSOPHY OF EDUCATION.) It is no accident that his two chief treatises on the right organization of social life (*The Republic* and *The Laws*) are also chief authorities for his ethics, metaphysics, and educational theory. He retains and continues the Socratic notions that right conduct presupposes true knowledge, and that the theory of true knowledge (logic or dialectic) is of practical or moral importance since it is a necessary instrument in bringing men to a consciousness of ignorance and opinion, with their attending evils, and in providing them with the means of attaining the knowledge that leads to the good. The genuine practice of dialectic as distinct from the spurious (eristic and sophistic) is thus an integral part of right living. Philosophy is thus not merely theoretical exercise, but defines the method of education, that is, of the conversion of the soul to the good and of the latter's progressive realization. Plato, in avoiding the sharp antithesis of knowledge and practice, also avoids the error, so common in subsequent thought, of making educational theory a mere external annex of philosophy.

2. Plato adds a distinctly new factor to the Socratic conception, in his conviction that knowledge is relative to social organization. That is to say, ignorance and mere opinion are inevitable in the degree in which self-seeking and division infect society, whether these are expressed in despotisms or in anarchic democracies. Such societies involve exclusive "particularity" of knowledge as the counterpart of the division of classes and interests.

Instead of affording the universality and permanence which are the patterns upon which true knowledge is modeled, they generate ignorance and casual opinions masquerading as truth. This strict correlation between right knowledge and right social organization involves, as its consequence, the equally strict correlation of educational theory and the theory of politics or sociology — the theory of the organization of the state. So far as the records indicate, Socrates had thought the conversion of the soul to true knowledge might be brought about by personal discipline independently of the action of the social environment.

This interdependence of true knowledge and the right organization of the state is Plato's answer, in anticipation, to the charge brought by Aristotle, and often repeated, that Plato overestimated the importance for right action of a purely theoretical knowledge, and ignored the need of habituation and practice. According to Plato, the attaining of the true theoretical knowledge itself implies and requires a long period of education in a social medium where the individual, acting in accord with principles of unity, balance, and harmony, absorbs into his practical habits the factors which make possible later on an independent theoretical vision. The Platonic social hierarchy, with philosophers at the top as social rulers, follows from his insistence upon social practice as an indispensable prerequisite for genuine knowledge. That Plato is caught in a circle, on the one hand insisting upon true, or philosophic, knowledge as a condition of right social organization and, at other times upon right social organization as an antecedent of philosophic insight, must be freely admitted. Since he had no conception of evolutionary growth, or gradual progress, he could not conceive that the true state should be ushered in otherwise than by a happy conjunction of circumstances; when once hit upon, it must be kept, at all hazards, intact against any further change, even in its minor details.

3. Plato clearly perceives, what later intellectual specialization obscured, that the motive and principle of the organization of the sciences is educational. The various sciences may be literally said, in accord with the Platonic spirit, to be *studies*; their differentiation and coordination is an affair of specifying the subject matter of an adequate education and of designating the proper aim of each branch of knowledge in the educational whole. A purified music and gymnastic (the customary content of Greek education) pave the way for the new studies of nature (astronomy and physics in the form of cosmology); these pass insensibly into mathematics; mathematics into dialectic; dialectic culminates in the apprehension of the final ends, centering in the conception of the Good, whence a reverse, or deductive, movement leads back to the study

of politics and ethics. There is, of course, much in the specific content of this account that subsequent philosophy and science have rendered untenable. But the underlying idea that the distribution and correlation of the various sciences is ultimately an educational matter, not an abstract intellectual one, must be regarded as a permanent contribution.

4. Plato states and treats the problem of the place and relations of the individual in society as an educational problem. Society is a complex unity; it involves the active coöperation of a number of diverse functions. Individuals are born with distinctive capacities. From one standpoint the need is that these various individuals' capacities be distinctively harmonized with a coordinated, unified social unity. From another standpoint, the need is that every individual be trained to intensity and efficiency of action in the particular capacity which distinguishes him by nature. The unity and order of the state suffer when individuals, instead of sticking to the single function for which they are naturally equipped, assume a multitude of activities, thereby encroaching on the sphere of others and introducing conflict into the social whole. Education supplies the means of satisfying the need from whichever side it be regarded. The business of education is to determine the social office for which individuals are fitted by a continuous process of selecting, sifting, and testing, in which the special talents and limitations of each individual are revealed. Practically, there is some truth in the complaint that Plato sacrificed individuality to the supposed requirements of social unity and stability. In theory, however, he held that the discovery of the special capacities of an individual so as to hold him to an occupation that should utilize his powers in the interests of the social whole was the sole method of securing both the true happiness of the individual and the good of the state. The education that discovers and trains the peculiar powers of an individual is at the same time the method by which intrinsic, instead of coerced, harmony is achieved in the state. This conception appears to present a permanent factor in the problem and ideal of education. The limitations in the Platonic treatment are due to the fact that he held the individual variation down to certain fixed limits and types, which corresponded to certain fixed classes in the state. Having the idea of a small number of classes within which variations in individuals fall, he was also led to the notion that the corresponding social classes have to be arranged in an order of inferiority and superiority. Advance since the time of Plato is in the direction of recognizing that individual variations are of the very heart of individuality itself, and that accordingly the development of characteristically individual powers is destructive of the existence of fixed social classes. Variety of social

activities conspiring to a coöperative unity of result has thus been substituted for hierarchical subordination of classes as defining the aim of education.

5. The characteristic rôle, already alluded to, of the æsthetic and the artistic in education represents another permanent contribution. The æsthetic and artistic provide the connecting link and the solvent factor with respect to the relation of the practical and the theoretical in education — an idea which is at the basis of Schiller's conception of education. On the one hand there is the need of practice, of repeated exercise, of habituation in education. This, by itself, tends to routine, and thus to a limitation of rational insight. But not so, if it is based upon spontaneous, uncoerced tendencies — upon play instincts. In this case, education, even as habituation, or practice, involves the emotional attitudes of the individual and an æsthetic subject matter which, through its inherent content of proportion, harmony, balance, and nobility, effects an insensible transition to rational insight. The treatment of gymnastic as well as of music is directed by this principle; Plato's well known attack upon poetry and dramatic art is based not upon a depreciation of the educational function of art and æsthetic appreciation, but upon his belief in their supreme educational significance and the consequent need of their supervision and control in the interests of the state. PLATTER, THOMAS (1499–1582). — Swiss scholar, printer, and teacher, chiefly known through his autobiography, which is written in a very quaint and interesting style and forms a valuable document for the history of education in the sixteenth century. He was born at Grenchen, in the canton of Valais, and spent his early youth as a goatherd. Then he was taken out into the world by a cousin and, as traveling scholars, they roamed for years through Saxony, Silesia, and Bavaria. The description of their roving life and their adventures affords a remarkable picture of the times. Platter finally found a home in Zürich, in the house of the schoolmaster Myconius. There he studied Latin, Greek, and Hebrew, but at the same time learned the trade of a ropemaker. In Zürich he also embraced the doctrines of the Reformation, which had been introduced by Zwingli. From there he went to Basel, where he worked at ropemaking and, in his spare time, delivered lectures on Hebrew grammar at the university. Later he established a printing press at Basel. In 1541 he was put in charge of the

Basel school, where he taught for nearly forty years, until he was retired in 1578.

PLAY. — A name given to those activities which are not consciously performed for the sake of any result beyond themselves; activities which are enjoyable in their own execution without reference to ulterior purpose. For a long time the theory of play most generally held was that most thoroughly elaborated by Herbert Spencer; namely, that play represents the overflow of superfluous energy, the base line from which to measure excess being the amount of energy required to maintain the level of health and perform imposed tasks. Since children are relieved of most of the duties connected with getting a living, they naturally have a relatively larger amount of excess energy at disposal. Since the channels of the discharge of the superfluous energies are those of necessary and useful works, it is not surprising that plays largely simulate practical activities. The more prolonged study of the plays of animals and savages impressed Groos with the extent to which plays represent acts that are useful in later life. He formulated the idea that the chief thing about play is that it gives preparatory exercise in later necessary functions. This is usually regarded as a rival theory to that of "surplus energy," but it is evident that the theories are framed from different standpoints and have no point where they touch each other. One theory might be correct as an account of the causal conditions of play, and the other as an account of its value.

As a matter of fact, however, the theory of surplus energy seems to be influenced by a survival of the once general conception that individuals are naturally averse to any kind of activity; that complete quiescence is the natural stage of organic beings; and that some fear of pain or hope of pleasure is required in order to stir individuals to effort which in itself is painful. The fact of the case is that from intra-organic stimuli, the organism is in a constant state of action, activity indeed being the very essence of life. When the myth of natural quiescence is surrendered with its accompanying myth of the need of a special premium in order to arouse an inert agent, it ceases to be necessary to search for any special cause or any special object order to account for play. The only thing necessary is to state the conditions under which organic activity takes this or that form. So considered, we find various forms, which are of sufficient importance, educationally at least, to justify differentiation; namely, play, amusement, art, work, labor, drudgery.

PLAY

In any case the starting point is the active processes in which life manifests itself. As stimuli direct this activity one way or another, some of its modes are peculiarly rewarding. The stimulus not only arouses a certain kind of activity, but the responsive activity returns upon the stimulus so as to maintain it and to vary it. These variations supply the stimuli for keeping up more action. The moving spool draws the organic response of the kitten to itself; this response continues to give the spool the kind of movements which continue to excite organic reactions. There is no difference in kind between the spool as a stimulus and a mouse, save that the latter has peculiar stimuli of the sense of smell and, when crunched by the teeth, of taste, that call out special responses. In like fashion, a baby plays with certain stimuli so as to keep up, with certain variations, a certain mode of action. Seeing a thing in a certain way evokes responses that make further seemings enjoyable.

After such processes have been frequently repeated, they are complicated by the fact that an idea of the result of prior activities is superadded. It may be that the idea of this result as a possible outcome will be a sufficient stimulus to keep the activity going after it has ceased to afford adequate stimuli so far as its direct results are concerned. If the idea of the result operates as a stimulus to renew the otherwise flagging activity, and if, in addition, the accomplishing of the result involves a certain selection and arrangement of acts antecedent to it, we get a type of activity sufficiently contrasted to be termed work. But as action involving the idea of an end grows naturally out of a spontaneous activity, so "work" in this psychological sense is inevitably preceded by play and grows insensibly out of it. The chief point of difference is not the agreeableness of one and the disagreeableness of the other, but that in the case of work the idea of an end enforces reflection on the relation of means to end, and stimulates a corresponding readjustment of activities originally spontaneous. Not only is the satisfactoriness of the activity not the main differentia, but, with increasing complexity of powers, prior activities are too simple to afford the necessary stimulation (and hence the desired satisfaction) unless they are expanded by a less immediate and more indirect adjustment of means to ends. At one stage of development, the relation between end and means is so close that if the dominating idea is that of playing "set the table," anything will be turned to account for a table and for dishes. With maturity of perception, the activity is not sufficiently complex to be enjoyed unless things can be devised and employed that are objectively adapted to the end. Action requires a greater amount of intellectual control and of practical check in order to be satisfactory, or worth

PLAY

while. At this point, and not at that of utility *versus* freedom, or of that which is an end for itself *versus* that which is a mere means for something else, lie the differentia between play and work.

Further distinctions are due to social conditions. The stimuli to activity become more social as intelligence develops. The interests and occupations of adults are the points of departure and the directing clews of children's actions. (See IMITATION; and INFANCY.) Certain plays have outcomes and methods that are determined by social conventions; such plays, carried on by rules, are games. But the distinctions of amusement, labor, and drudgery also arise from social conditions.

Labor is a fact of economic origin. Wherever industry is subdivided, as it is beyond the fishing and hunting stage of civilization in greater or less measure, the product of work is not a direct stimulus to the prior process, for this product is not itself enjoyed or consumed, but is exchanged for another object (or for money). This means that the direct end of action is not its adequate stimulus; that something not directly cared for is done for the sake of a more ulterior end. This implies the possibility at least of the direct activity being itself so disagreeable that there is an aversion to it, which is overcome only because of the need for the ultimate object. Under certain conditions of economic life, labor almost inevitably takes on this externally enforced quality, and, as it is intrinsically irksome, becomes drudgery. The notion, referred to earlier in this article, that man is naturally averse to action and hence is moved to it only by fear of evil or love of reward, was taken into psychology from economic theory at a time when industrial life consisted mainly in wage-earning under conditions themselves repulsive. Amusement is differentiated from play by a sort of contrast effect. Children do not normally play for the sake of amusement, any more than for the sake of any end beyond the action itself. They live in their actions, and these actions are called play because of certain qualities they exhibit. But adults (as well as children whose surroundings are socially abnormal) need relief from labor, especially from drudgery. Powers not used at all, or used under enforced and distorted conditions during working hours, need stimulation. The things outside the ordinary routine activity of labor that yield this stimulation constitute amusements. The fact that they are called recreations and are employed for purposes of relief indicates a contrast-effect not normally present in the play of childhood.

It is also desirable to distinguish an attitude of mind as playful. Matthew Arnold, for example, called ability to occupy the imagination fruitfully with a subject, the ability to allow the mind to play freely about the subject, a sign of culture. This attitude of mind is

distinguished from inability to enjoy intellectual activity upon a subject except in the interest of some preconceived theory or some practical utility. This capacity to draw satisfaction from the immediate intellectual development of a topic, irrespective of any ulterior motive, represents a genuine outgrowth of the play attitude—a special form which it may take. Unless play takes this intellectual form, the full spirit of scientific inquiry is never realized; much, if not all, of what is termed the love of truth for truth's sake in scientific inquiry represents the attitude of play carried over into enjoyment of the activities of inquiry for its own sake. The putting forth of observation, reflection, testing, is enjoyed on its own account, irrespective of ulterior by-products, just as in early childhood certain strenuous and even hazardous forms of physical effort may be intrinsically satisfactory.

Play and Education.—The account that has been given indicates, in outline, the chief educational problems connected with the topic of play. The original discovery of its importance in education, by Plato, and its rediscovery by Froebel, may be said to constitute the basic principles of the method of instruction. The foundation of all later growth is the activity of the earlier period, which, so far as the consciousness of the individual is concerned, is spontaneous or playful. Hence the necessity that the earlier plays be of such a sort as to grow naturally and helpfully into the later more reflective and productive modes of behavior. This means that play should pass insensibly into work (though not necessarily into labor), and that earlier play and work alike be of the kinds which afford exercise in the occupations that are socially useful. For a genuine initiation into them through play means not only that the individual has acquired, under conditions of least resistance and greatest economy, the skill required for efficiency judged from the social standpoint, but that he has done so through the engaging of his own imagination and emotions. In other words, the natural transition of play into work is the means and the only means of reconciling the development of social efficiency with that of individual fullness of life.

Other educational problems arise from the economic conditions under which industry is carried on at present, with its extreme specialization of labor and its control by reference to a medium of exchange instead of by commodities valued on their own account. It is a part of the business of education to fortify and enrich the imagination so that the mechanical phases of industry shall not leave an unformed mind at the mercy of sense, appetite, and trivial fancy. It is a part of its business to come into sufficiently close contact with the conditions of industry so

that those who go from school into industry shall be trained to understand the whole of which their work is a small fraction, and thus to see a meaning in their work which they could not otherwise perceive. Moreover, it is necessary that the plays and games of the school should be so directed as to instill a love for and capacity in wholesome forms of recreation and amusement. Perhaps there is no more neglected aspect of social education at the present time than just here. Because amusement is contrasted with serious things we have forgotten that the function of recreation, of the spending of the hours of leisure, is one of the most serious questions, intellectually and morally, of life, and that any educational system is defective which does not make systematic provision for this as well as for the hours of work. PLAY CENTERS.—See PLAYGROUNDS.

PLAY, FREE.—In the kindergarten the use of materials to stimulate free response on the part of the child, i.e. to insure self-activity, is an activity of free play. The term is opposed to directed play, where there is selection from the responses of free play for the purpose of increasing the educative value of the activity.

See KINDERGARTEN; PLAY.

PLAY, HYGIENE OF.—See PLAY; PLAYGROUNDS.

PLAYFAIR

PLAYFAIR, LYON (1808-1898).—English scientist and politician, responsible in large measure for the introduction and spread of technical education in England. He studied at St. Andrews University, the Andersonian Institute at Glasgow, the University of Edinburgh, and at Giessen under Liebig, whose book on applied chemistry he presented at the British Association meeting in 1840. Always interested primarily in applied chemistry, he was appointed by Peel on a commission to inquire into the sanitary conditions in large towns. He played an important part in organizing the Exhibition of 1851 and came into close touch with the Prince Consort, who was interested at the time in promoting technical and scientific education in England. Playfair about this time visited the Continent to study the organization of technical instruction, and on his return lectured on the subject in England. He was largely responsible for the foundation of the Science and Art Department, of which he became one of the secretaries (1853). He also took a large share in establishing the Royal College of Science, the South Kensington Museum, and the 1851 scholarships for science. In 1858 he was appointed professor of chemistry at Edinburgh. In 1868 he entered Parliament as representative of the Universities of St. Andrews and Edinburgh, and 1885 as member for South Leeds. He held office several times, and in 1892 was raised to the peerage. Playfair used his influence in Parliament in favor of education and social improvement. Among the many commissions and committees of inquiry on which he served may be mentioned those on the Scottish universities, on endowed schools, and on civil service reforms (Playfair Commission, 1876).

PLAYGROUNDS.—Plots of ground set aside for the holding of games, sports, athletic exercises, and amusing activities of various sorts. In the United States the deliberate provision of these areas was begun in 1886 when "three piles of yellow sand were placed in the yards of the Children's Mission," in Boston. The next year this society established eleven sand piles—one being in a school yard,—and special matrons to look after the children enjoying them were employed for the first time. With the growth in the number of the playgrounds they also became larger, new games appeared, and teachers trained in kindergarten methods were put in charge of them. In 1893 two summer playgrounds were started by philanthropic people in Philadelphia. The Children's Kindergarten Association started sand gardens in Providence, R. I., in 1894. About the same

PLAYGROUNDS

time several private playgrounds were started in New York City, but the movement did not really get under way until 1898, when the board of education, on taking over the vacation schools of the Association for Improving the Condition of the Poor, established twenty school playgrounds or sand gardens. The first summer playground in Chicago was started in 1897 through the efforts of the Associated Charities. Since that time the spread of the playground movement has been rapid. During 1911, according to reports received by the Playground and Recreation Association of America (75 cities known to have playgrounds did not report), playgrounds were maintained in 257 cities of the United States, the total number of such grounds being 1543. On their staffs, not including the caretakers, were 4132 men and women. The total expenditure for maintenance amounted to \$2,736,506.16. In 36 of these cities the playgrounds were kept open throughout the year. Public parks, school yards, and vacant lots are the usual sites, but some of the larger cities conduct playground activities on specially constructed piers along the water front, and in the basements and on the roofs of schools and other large buildings.

Equipment.—The facilities provided vary greatly in character and quantity in accordance with local conditions. In Chicago, where the playgrounds form integral parts of an extensive park system, the typical layout includes a field large enough for baseball or football; a field house having a refectory, reading, club, and assembly rooms; indoor and outdoor gymnasiums for each sex; a large swimming pool for adults and a wading pool for small children. The latter forms the center of the children's space, which is equipped with sand courts, swings, teeter boards, slides, giant strides, and similar apparatus. The main field can be flooded in the winter for skating, and electric lights make it possible to use the large swimming pool by night as well as day from spring until fall. While such ample facilities are rather unusual, they indicate the kinds of equipment which in varying degrees of completeness are found in the park playgrounds throughout the country.

A typical school-yard equipment consists of several swings and teeters, a sand pit, a frame swing, basket-ball standards, a tether ball equipment, a net for volley ball, a standard for high jumping, a springboard, and a supply of playground balls, also materials for sewing, basket making, and raffia work. In many yards only jumping standards, horizontal bars, and sand piles are to be found, and in general more dependence is placed upon organization than equipment when the playground is managed by school officials.

The principal playground activities have been sufficiently indicated by the description of the equipment. Among those which are

A Public Playground, East Orange, N.J.

A School Playground, Detroit, Mich.

A Public Playground, Haarlem, Holland.

Assembly Hall in the Field House of a Public Playground, Chicago, Ill.

A Park Playground, Chicago, Ill.

Roof Playground, Public School Building, New York City.

PUBLIC PLAYGROUNDS

PLAYGROUNDS

also found may be mentioned various kinds of hand work, gardening, story-telling, singing, folk dancing, amateur theatricals, pagants, and club work frequently of the self-governing type. Sometimes the playground is the headquarters of boy scout patrols and camping parties. The nature of the work carried on by the New York Board of Education is shown in the following program:—

NEW YORK DAILY PROGRAM

1.00-1.30 Assembly	{ Marching Singing Salute to the Flag Talk by the Principal
1.30-2.30 Organized Games	{ Kindergarten Gymnastic
2.30-3.00 Organized Free Play	
3.00-4.00 Drills	{ Gymnastic Military
Folk Dancing	
Apparatus Work	{ Raffle Clay Modeling Scrap Books
Occupation Work	
4.00-4.45 Organized Games	{ Kindergarten Gymnastic
4.45-5.15 { Basket Ball Athletics	
{ Good Citizens' Club	
5.15-5.30 Dismissal	{ Marching Singing

Roof Playgrounds.—The utilization of the roof as a playground is made possible by paving the surface and erecting light steel trusses over which is spread a coarse wire netting. The schoolhouse roofs in New York City which are used by the boys in this way are equipped with basket-ball hoops and marked off for tennis and indoor baseball. Those for the girls usually have no apparatus, as the principal activity is that of folk dancing. Music is provided by a band of four or five pieces, and sometimes (during the hot summer evenings), as many as 2000 girls assemble on one roof. In the afternoons some of these spaces are enjoyed by the smaller children, who are frequently accompanied by their mothers, and swings, seesaws, sand boxes, and slides are provided. Through the furnishing of seats, flower boxes, hammocks, and pavilions the roofs of some of the more modern tenements, apartment houses, hotels, and other institutions in the large cities are being converted into roof gardens and outdoor play spaces.

The recreation piers, which have been established in several large cities, have the form of huge pavilions, and the activities carried on in them are mainly folk dances, marches, and ring games. Certain of the piers are equipped with hammocks and folding cots for babies and play outfits for very small children, and these, under the management of trained nurses, are effective in reducing infant mortality during the hot season.

Administration.—The duration of the playground season varies greatly, but in general it

PLAYGROUNDS

coincides with the warm months. In park systems where there are field houses, it frequently lasts throughout the year, and in a few cities the privileges are open on Sundays as well as week days. School playgrounds are usually open from 1.30 to 5.30 p.m. during six or eight weeks of the summer, but there is also a tendency to make their facilities available after class hours during the regular school term. The staff at some of the larger park playgrounds numbers from fourteen to twenty specially trained play leaders and gymnasium instructors, but in general the number is from four to six. In systems under municipal control the employees are usually selected by civil service methods. The instructors in the Chicago park gymnasiums receive \$1100 a year, while in New York the principals of the school playgrounds receive \$4 a session, and the assistants' rates vary from \$1.75 to \$2.50 per afternoon. Throughout the country the usual rate of pay for a qualified play leader is about \$2 a day. The technique of the work has become so highly elaborated that a special training is now indispensable, and many colleges and normal schools are giving courses in the theory and practice of play and in playground administration.

The administration of about one half of the American playgrounds is still in the hands of the voluntary agencies, principally known as playground associations, through whose initiative they were started. In over one fourth of the cities they are managed by the park department, in one sixth by the school board, while in the remainder they are under the control of municipal playground or recreation commissions. The novel and special character of the problems involved, with the diversity of the recreational resources in the average community, makes it desirable that the administration be in the hands of persons with an enthusiasm and proficiency for its tasks. If they form an independent body they can secure coordination in the management and economy in the use of the various facilities for play possessed by the park, school, dock, and other departments of the municipal government. The prime motive back of the playground movement was to increase the amount of *space* for play, and accordingly the activity has been greatest in districts congested by population. The reinforcement of this motive by the obvious moral and educational values of directed play has made it relevant to all kinds of population conditions, and the movement is now extending not only to the small cities, but also to the towns and villages and even to the rural districts.

Results.—Among the more conspicuous effects which have been traced to playground work are a reduction of juvenile delinquency, a lessening of street accidents to children, an improvement in the racial relations in communities largely populated by foreigners, and

a quickening of mental power among school pupils. The popular demand for playgrounds is tending to increase the size of school yards and the provision of bathing and gymnasium facilities in the school buildings.

European Playgrounds.—Abroad the emphasis has been placed upon the organization of play rather than upon the extension of places for it. The efforts are made almost entirely by voluntary agencies, though these, especially on the Continent, frequently receive considerable financial support from municipalities. In England the education authorities of a score or more of cities grant the use of school grounds, buildings, and public parks to such organizations as boys' and girls' brigades, scouts, Children's Play Centers committees, and Children's Happy Evenings societies. In a few cases the authorities are also giving financial aid, but usually the provision of apparatus and organizing ability comes from the voluntary organizations. On the Continent the most active agents are the Central Committee for the Encouragement of Games in Germany, the Society for the Promotion of Games of Vienna, the German Society for the Promotion of Organized Play at Prague, the *Comité des écoles de garde* of Paris, the Society for Open-air Games of Gothenburg, Sweden, and the Swiss Society for Games and Excursions. PLURALISM.—The opposite of monism (*q.v.*); the theory according to which there are a number of independent ultimate principles of reality or real beings. It includes systems as diverse as the atomism of Democritus, the monadism of Leibnitz and Herbart, and the radical empiricism of William James (*qq.v.*).

J. D.

PLUTARCH (c. 46-125 A.D.).—One of the greatest teachers, historians, and moral philosophers of antiquity, who was educated at Athens and traveled extensively. He spent some time at Rome, where he lectured on ethics, acted as tutor of the youthful Hadrian, and collected historical materials. Returning to Greece, he organized a school at Chæronea, his birthplace, where for many years he lectured to the young and composed dialogues after the manner of Plato and Cicero. Here he carried on his historical studies and wrote his *Parallel Lives*. These embodied the results of enormous erudition and research. Their purpose was chiefly ethical, and they exerted a powerful influence in upholding the highest Greek and Roman ideals of conduct. They formed the basis of Roman education in both home and school for many generations and furnished Shakespeare, Milton, Browning, and other modern writers with materials for some of their greatest works. His *Opera Moralia* consists of sixty didactic essays, the first of which, *On the Education of Children*, is an educational classic. It is the oldest extant treatise entirely devoted to education. Plutarch insists upon the importance of heredity and a good example from parents; argues that the schoolmaster must be of blameless life, pure character, and great experience; subordinates all advantages of rank and fortune to education, of which philosophy should be the chief study, but not to the neglect of science; approves of the higher education of women in order that they may help in the education of their children; and recommends that paternal discipline should be long and thorough.

POITIERS, UNIVERSITY OF, FRANCE.

—Founded in 1431 by Charles VII to draw students away from the University of Paris, then in the hands of the English. The University constitution was modeled on that of Toulouse (*q.v.*), a compromise between those of Paris and Bologna. There were originally faculties of law, theology, medicine, and arts. The first mention of statutes appears in 1488, but they were revised in 1553, and remained in force until the Revolution. The University was at no time of great eminence, and it was already in a condition of decadence when it was closed at the time of the Revolution. The law faculty was restored in 1806, followed in 1846 by the faculty of letters, and in 1856 by the faculty of science. In 1841 the *École de Médecine*, now the *École Préparatoire de Médecine et Pharmacie*, was established. The enrollment at the University in 1911 was 1135 students, of whom 875 were in law.

See FRANCE, EDUCATION IN.

POLAND, EDUCATION IN.—History.—

The division of the territory of Poland between Russia, Prussia, and Austria, which was accomplished in 1795, ended the independent existence of one of the oldest and, for a time, one of the most powerful kingdoms of Europe. Its history begins to take definite form in the latter part of the tenth century, when Christianity was forced upon the people by King Miecyslaus I. For centuries following this kingdom served as the bulwark of Europe against Mongolian, Tartar, and Turkish hordes, and eventually as the "Champion of Christendom" against the Moslem power. The early history of education in Poland is a record of clerical and cathedral schools, of monastic schools maintained by the order of the Benedictines, who were invited to establish themselves in the country, in the eleventh century, by King Boleslaus the Great, and of the rise of town schools in the thirteenth and fourteenth centuries,—the result of German migrations into the centers of trade and industry. As in the other European nations the studies of the principal schools were those of the trivium and quadrivium, and the language of instruction was Latin; but the Polish language appears to have been used conjointly with the Latin, and the German language in the schools established by German settlers.

Both the weakness and the strength of Poland and the character of its national education were due to its political structure, which was

that of a feudal aristocracy or aristocratic republic. The nobles from the beginning had absolute power over their serfs, and their restraint upon the authority of the king steadily increased until he became merely their agent. Education was the privilege of the nobles and reflected their spirit. Toward the close of the twelfth century, the sons of the nobility began to frequent the universities of Italy and France. In the thirteenth century they were sufficiently numerous at the University of Paris to form a "nation." Thus intellectual attainments were added to the military prowess for which the nobles were distinguished. The fourteenth century was marked by the extension of the power and the territory of Poland. Wealth increased through the commercial activity of the great towns, two of which, Dantzic in the north and Cracow in the south, at this time the capital, joined the Hanseatic League; Warsaw and other towns on the Vistula sprang into importance. The political constitution of the nation, as an aristocratic republic, was defined by statutes passed during the reign of Casimir III (the Great). The supremacy of the nobles was confirmed by these acts, but their power of life and death over the peasantry was abolished, and a degree of civil independence was assured the towns. The national Diet also assumed form at this time, the nobility and higher clergy having chief representation therein, although merchants and the inferior clergy were admitted; the principle of hereditary succession to the crown was ultimately eliminated, and the sovereign was elected by the Diet.

Education naturally engaged the attention of a lawgiver like Casimir the Great, and in 1364 he laid the foundations of the first university in Poland, at Cracow, having the purpose of creating a great school after the model of Bologna. The statute authorizing the institution was published on Pentecost of that year, but its actual operations were deferred for over twenty-five years. Casimir the Great died in 1370 and, having no direct heir, he was succeeded by his nephew, Louis of Hungary. This event increased the foreign relations of Poland and introduced new ecclesiastic and scholastic influences. After the death of Louis, in 1382, his second daughter, Jadwiga, was elected sovereign, but upon the condition that she should take, for her husband, a prince chosen by the diet. As a consequence of this agreement she was married, in 1386, to Jagiello, prince of Lithuania, thus effecting the union of this principality with Poland. The new territory stretched from the Baltic to the Black Sea and eastward to Moscow. Its religion, that of the Greek Church, and its official language, White Russian, were brought by the union into immediate contact with the Roman Church and the scholastic Latin. In 1402 the University of Cracow (*q.v.*) was inaugurated with great ceremony and under strong ecclesiastical influences, Paris,

instead of Bologna, being the model. Queen Jadwiga, who died in 1399, had left her fortune for the university; and it was richly endowed by the king and the bishop of Cracow. With the introduction of printing, the city became the center of literary activity, in the midst of which the university enjoyed great distinction by reason both of its valuable library and of its learned members. In the sixteenth century it gave to Poland the historian Jan Dlugosz, the mathematician Albert of Brudzen, and his immortal disciple, Copernicus.

The dynasty of the Jagiellos continued with a brief interruption nearly to the seventeenth century, when the throne became entirely elective. Under the successive rulers of this house there were repeated conflicts with the Germans, the Turks, and the Russians, and those hatreds were engendered which eventually proved disastrous to Poland's national life. During the same period the power of the nobles was constantly augmented through their control of the Diets. The elements of discord within the kingdom were increased by the spread of the Lutheran doctrines, which were accepted by the order of the Teutonic knights, and rapidly transformed the German schools. Rival schools increased their activity, and under Sigismund II, who reigned from 1548 to 1572, religious animosity gave rise to fierce persecutions.

The University of Cracow yielded nothing to the new religious doctrines and was unmoved by the spirit of the Renaissance, which was transforming the universities of Western Europe; consequently the Protestants established higher schools of their own. Two of these, created in the sixteenth century by the Calvinists of Lithuania, at Kiejdany and Slutsk, respectively, are still in existence. The Bohemian brothers established a higher school at Lissa, which numbered among its directors John Amos Comenius. It was probably to offset this movement that the Bishop of Varnie, in 1564, invited the Jesuits to open colleges in his diocese. From this time to the middle of the eighteenth century the influence of the Jesuits was supreme in educational matters, but eventually they gave place to the Piarists (*q.v.*), who entered into the field in 1596. The schools of other religious sects, the Lutherans, Greek Church, etc., merely reached their own adherents. Thus through the divergence of ideals the educational provision of the country tended to destroy the sense of national unity. The situation is illustrated by the following summary of schools and higher institutions for 1740:—

<i>Catholic Universities</i>	
(Cracow, Zamosc, Vilna)	3
<i>Secondary Schools</i>	
Preparatory to Cracow and Zamosc	10
Preparatory to the Jesuit University, Vilna	87
Controlled by Piarists	27
Controlled by Protestants	5
Total	112

In the higher and secondary institutions there were 22,400 students and in the 1500 elementary schools above 30,000 pupils.

The great body of the people at this time were in a state of ignorant servitude; only the nobles, the merchants, and a very small proportion of the free peasantry were instructed; the nobles constituted the nation, but a nation broken by religious dissensions and feuds, and menaced by hostile forces on every side. In this crisis the reform of education was undertaken by Stanislas Konarski, a Piarist priest who had been a student in the famous Nazarene college at Rome. After completing his studies he made a tour of France and came into intimate relation with Charles Rollin, who had completely reformed the higher schools of his own country. Encouraged by this example, the Abbé Konarski, on his return to Poland, established a school of a new order for the young nobles, the *Collegium Nobilium*. Its curriculum comprised the exact sciences, physics, astronomy, mathematics, geography, universal history, the history of Poland, and the classics in restricted degree. The influence of the college was supplemented by that of the "school of cadets," which was established by Stanislas-Augustus Poniatowski, soon after his election to the throne in 1764. Although this king appears to have been a mere puppet in the hands of the Empress Catherine of Russia, the military school became a nursery of nationalism. Among its cadets was Kosciuszko, chief of the band of patriots who sought to free their country from foreign invaders. The educational reform was opposed by the Jesuits; but the disastrous contests of 1772, in which Prussia and Austria wrested entire provinces from Poland, gave irresistible force to the national movement. It was fostered by Rome as the only check to the encroachments of Russia and the Greek Church, and by Papal Bull of July 21, 1773, the order of the Jesuits was suppressed, and their confiscated properties were turned to the service of the reform movement. A few months after this event, the Diet created a Commission of Public Education and to it committed the charge of all the schools, colleges, and universities in the country. The secretary of the Commission was Gregory Pyramowicz, a Jesuit, but in full sympathy with the reform movement. The measures advocated by this commission anticipated many of the more important provisions of modern systems. The universities were transformed, normal schools established, and laws were enacted (1783-1790) regulating the entire service of public instruction. In the colleges the Polish language replaced Latin as the medium of instruction; the sciences and civil and ethical subjects took the place of the scholastic philosophy and metaphysics, and observation and experiment broke up the old routine of memoriter recitations. A special

committee was appointed to secure a new order of textbooks, and provision was made for the systematic inspection of elementary schools and for supplying them with trained teachers.

Thus, on the eve of its destruction as a nation, Poland bore an important part in the educational reforms of the eighteenth century, and its school law remains a lasting memorial of its awakened national spirit. In 1792 the second partition of the country was effected; and in 1795, the third division, which ended the ancient kingdom of Poland.

The Divided Kingdom.—Since the division the Prussian government has suppressed the use of the mother tongue in the Polish schools, which have been gradually and completely Germanized. The similar attempt in the Austrian division was abandoned in 1867, and the Polish language was restored as the medium of instruction; and at present the educational conditions in Austrian Poland are comparable to those of Western Europe. In 1910, beside the two universities, Cracow and Lemberg, the polytechnic school and several technical schools of a lower order, there were in this division 84 secondary schools, with 34,853 students, and 5036 primary schools, enrolling 953,500 pupils, for a population of 3,982,033.

The Grand Duchy of Warsaw.—The Grand Duchy of Warsaw, formed by Napoleon from Polish provinces of Prussia under the treaty of Tilsit, 1807, continued the movement started by the Education Commission of Poland. In 1814 the Grand Duchy was united with Russia, and by the agreement of the Congress of Vienna, 1815, it was organized with other territory as a constitutional kingdom subject to the Czar. To this division of the ancient kingdom the name Poland is still applied. It comprises an area of 49,157 square miles and in 1909 had a population of 11,671,800.

Russian Poland.—The kingdom of Poland within the Czar's domain was given a separate educational system under the control of a Commission of Worship and Public Instruction. For a few years the former director of education in the Duchy of Warsaw, Stanislas Patocki, was retained as chief of the commission, and the progressive movement continued. During his administration, the University of Warsaw was created, 1816, and the following year it was opened with imposing ceremonies; a higher technical school and several middle technical schools were established, and secondary schools and primary schools multiplied; but reactionary influences set in and the futile revolt of the Poles in 1830 resulted in the reduction of the "Congress kingdom" to the state of a Russian province. From that disastrous year to a very recent date, the history of education in Russian Poland is a history of suppression and conflicts, excepting for a brief respite during the administration of the Marquis Alexander Wielopolski, a

Polish nobleman who was appointed Director of Education in 1861. Moved by his counsels, the Emperor Alexander II issued the decree of May 8, 1862, reestablishing, in a measure, the educational policies of the Duchy of Warsaw. The work thus revived was terminated by the second and fatal revolt of the Poles in 1863.

Officially Poland no longer exists. After the suppression of the second revolt, the Russian division was designated as the territory of the Vistula, and later as the Vistula government. Throughout its whole extent the Russification of Polish institutions has been enforced with relentless severity. The use of the Polish language as the medium of instruction was prohibited in the secondary schools at first, and finally even in the primary schools and the Polish university at Warsaw was transformed into a purely Russian institution. This policy of suppression was embodied in successive ukases and administrative orders which were ruthlessly executed by the Russian teachers and supervisors appointed over the Polish schools. The resistance of the Polish people culminated in 1905, when the whole body of Polish pupils withdrew from the schools. Parents came together in a great public assembly and sustained this action, and finally the entire force of teachers joined in the protest and with one voice petitioned for the right to establish private schools under the control of the Polish society, in which the native language should be employed and the history and geography of Poland included in the curriculum. The Russian government yielded so far as to authorize the maintenance of private schools without the privilege of the government examinations and diplomas. The following year a law was passed which legalized private societies and thus opened the way for the remarkable development of social self-help which has characterized the last few years in Russian Poland.

Most prominent among the societies which sprang into existence was the *Macierz Szkolna* (Mother of Schools), which after vigorous and successful work was dissolved by an order of Dec. 15, 1907. The corporation of merchants at Warsaw also established many schools. The chief private schools are models of construction, equipment, and hygienic arrangements, and are provided with systematic medical inspection. Polish gymnastic societies for promoting school plays, school colonies, and manual work in schools, have also achieved excellent results in the last few years.

According to the last issue of the Year Book of Russia (1911) there were 6649 schools in this government in 1909, having an enrollment of 306,185 pupils distributed as follows: high schools, 1743; middle schools, 16,236; special schools, 15,725; primary, 272,481; but as the private schools are not included it is impossible

to form any idea as to the extent of school attendance on the part of the Poles. It is, however, significant that whereas the proportion of illiterates to the population above nine years of age in the other divisions of the Empire ranged from 70 to 93 per cent according to the last estimates (1897), in the Polish section it was only 59 per cent.

Higher Education.—The survival of the Polish national spirit through the century of dispersion and suppression is one of the most striking facts in modern history. It is a caste spirit intensified by heroic traditions embodied in a noble literature. The extent to which the Polish people attend school under present conditions is a question, therefore, of less significance than that of the institutions which still preserve the language and record of their national distinction. In the number of these must be included the University of Königsberg, established in 1544 by Albert, Duke of Prussia, for the purpose of promoting religious, literary, and scientific culture among the different peoples inhabiting his dominions. Failing in the effort to secure the sanction of the Pope, this Protestant university received a charter in 1561 from King Sigismund II of Poland. The special object of the theological faculty of the university was to train ministers who could teach the scriptures to the Polish and Lithuanian subjects of the duke in their native languages, and with these peoples its history and activities have been identified. The university still maintains a Polish "seminar."

Cracow and Lemberg, in Austrian Poland, are essentially Polish universities. The Imperial Academy of Sciences maintained in connection with the former is the present center of the highest intellectual activity of the Poles without regard to their geographic location. The University of Lemberg was a feature of the educational reform planned by the Empress Maria Theresa, which was not accomplished until 1784, a few years after her death. The university was completed under the present emperor in 1894 by the establishment of the medical faculty. Like the University of Cracow, Lemberg possesses a valuable library. Although the University of Warsaw has been transformed into a Russian institution, its library is especially rich in works of Polish literature, history, and law. The principal archives of the Polish kingdom are also at Warsaw. This city, capital of the Vistula government, is therefore the center of research in respect to a history which on account of interrelations is a matter of equal concern to all Slavonic and Teutonic nations.

POLIOMYELITIS.—See INFANTILE PARALYSIS.

POLITICAL ECONOMY.—See ECONOMICS.

POLITICAL EDUCATION.—See CITIZENSHIP, EDUCATION FOR; PATRIOTISM, EDUCATION IN.

POLITICAL SCIENCE.—Definition, Method, and Relation to Allied Sciences.—Political science (*Staatswissenschaft*) is defined by Bluntschli as "the science which is concerned with the State, which endeavors to understand and comprehend the State in its fundamental conditions, in its essential nature, its various forms or manifestations, its development." Some writers, especially in France, prefer the plural form, "the political sciences" (*sciences politiques*), arguing that there is no single science of the State, but rather a group of related sciences. The term "politics," used by many writers, is open to the objection that in popular usage it denotes the concrete and often partisan art of government, rather than the systematic study of political forms and phenomena. The term politics arose among the Greeks and referred originally to the government of the city (*πόλις*). With the decline of the city States and the development of modern national organizations, the term was correspondingly widened. The State, the institution with which political science deals, may be defined as a population which occupies a definite territory and which is politically organized by means of a government which formulates and administers, in the form of law, a sovereign will over all individuals and associations of individuals within the State, and which maintains a sovereign independence by adjusting the mutual powers and obligations of the State in its dealings with other States.

The scientific investigation of political phenomena is carried on under certain difficulties. The facts of history cannot be reproduced or made the subject of experimentation, and few artificial devices can be used to direct

or increase the observation of facts or the registering of results. Besides, social facts do not recur at regular intervals, nor follow invariable general laws. The influences affecting them are complex and closely interrelated, and the actions of individuals can seldom be accurately predicted. Accordingly, political science employs a variety of methods. Experimentation is carried on whenever the organization or activities of government are consciously modified. The biological method which attributes to the State the qualities of a living organism emphasizes the unity and continuous evolution of political forms. The psychological method, popular among French writers, interprets social phenomena in terms of psychological laws. The juridical method, favored by the Germans, views the State as a legal, rather than a social, institution, and draws its conclusions from an analysis of the State's relations in public law. The historical and comparative method aims to discuss the origin and development of political forms, and the laws of political causation; and by selection, comparison, and elimination to derive general principles from the mass of historical data. This method, probably the most fruitful, is also the most difficult, being especially liable to errors resulting from personal bias or from the omission of elements which invalidate the most important conclusions.

The growing realization of the fact that no science dealing with mankind has special data all to itself, and that political phenomena are not the manifestations of a distinct side of human nature nor of a distinct species of human beings, has emphasized the relations between political science and the other social sciences. Starting with those acts that are specifically governmental, political science works gradually through related acts into the general field of human conduct. From history it draws its data; in sociology it observes the development, structure, and functions of social institutions closely related to the State; in economics it finds that motives and action chiefly concerned with the production, distribution, and consumption of wealth, influence and are influenced by political forms and functions; in ethics it sees a close connection throughout the whole development of morality and of law. Modern thought accentuates relations rather than differences, and by utilizing the mass of materials gathered in allied fields, political science is no longer founded upon shifting speculations, but is possessed of sounder knowledge of the nature and tendencies of the State, can build up more scientific principles of political causation, and can make possible more rapid and rational political progress.

Historical Development. — To the historical development of political science two main influences have contributed. Rulers and

statesmen, in the work of practical government, necessarily conceive certain political principles upon which to base their actions. These are embodied in institutions, or are found, expressed or implied, in laws, constitutions, treaties, and state papers, in the writings and speeches of politicians, and in general public opinion. Such principles, often arising unconsciously, are seldom comprehensive or systematic, but are often full of prejudices, legal fictions, and inconsistencies. On the other hand, political philosophers, outside the current of actual government, have frequently attempted to build up theories of the State. Sometimes these have aimed to explain the origin of the State, to justify its authority, or to determine the scope of its activities. Again they arise to uphold or to attack certain existing governmental forms or methods. Sometimes these theories have been purely speculative or idealistic in nature. Again, they have resulted from the observation and analysis of existing or historical governmental institutions. Through a combination and interaction of these influences the science of the State has, in the main, developed.

Political speculation proper scarcely existed before the rise of Greek philosophy. In the Oriental nations thought was based upon tradition and belief rather than upon reason, and sufficient political liberty to permit questioning seldom existed. The Greeks, however, having no powerful priestly class and few fixed dogmas, viewed the State and law as "natural" in origin, as representing the highest form of life; and, in their small city units, developed considerable individual freedom and much keen thinking in politics. In the philosophical idealism of Plato and in the more scientific observations of Aristotle are found the best statements of Greek political theory. While the Romans took their philosophy, with little modification, from the Greeks, they worked out valuable practical principles of government. The ideas of positive law, systematic jurisprudence, sovereignty, citizenship, municipal and colonial administration, and world empire were among their contributions. They also emphasized the value of checks and balances, and of political compromises in securing stable government. Polybius and Cicero best state their theories. After the fall of the Roman Empire, the doctrines of the Christian Church and feudal customs based on landholding furnished the chief political principles, and medieval theory was chiefly concerned with the proper relation of Church and State. The papal party, represented by Gregory VII, Innocent III, and Thomas Aquinas, claimed superiority for spiritual power as more directly conferred by God. But by the fourteenth century the revived study of Roman law furnished principles for the defenders of civil power, and Dante and Occam supported the national monarchies

then arising. The Renaissance spirit in politics was represented by Machiavelli, who replaced scholastic deductions by actual investigation and comparison, and again brought political theory in touch with actual facts. He also divorced politics from religion, justified conquest, and recognized nationality. After the Reformation, Calvin's doctrine of democracy in church-government was applied by his followers in Holland, England, and America as a foundation for political liberty. (See CALVIN; CALVINISTS AND EDUCATION.) Meanwhile, the existence of a number of well-organized national monarchies, having relations one with another in war and peace, prepared the way for modern political science. Bodin, in the sixteenth century, made the first systematic study of politics since Aristotle; and in the seventeenth century Grotius (*q.v.*) laid the foundations of international law. In the writings of these men the modern theory of sovereignty as internal supremacy and external independence was established. The growing contest between king and people next influenced political theory. The doctrine of divine right upon which the absolute monarchies were based was upheld by James I and Bossuet, but was attacked by the growing belief in "natural rights" and in the "social contract" as the basis for political authority. Hobbes utilized this theory to support kingship, but in the hands of Locke and Rousseau the new theory paved the way for popular sovereignty. Montesquieu pointed out the influence of physical environment and emphasized the value of the separation of powers in government. In the nineteenth century the growth of historical knowledge and the biologic doctrine of evolution chiefly influenced political science. Modern political science, then, begins with Bodin, Grotius, Pufendorf, Hobbes, Locke, Rousseau, and Montesquieu. During the last century the science has been enriched by the work of numerous scholars, among whom may be mentioned Von Mohl, Waitz, Holtzendorff, and Bluntschli in Germany; De Tocqueville and Laboulaye in France; Lewis, Austin, Maine, Mill, Freeman, Sidgwick, and Sealey in England; and Hamilton, Madison, Lieber, Woolsey, and Burgess in America.

History of Academic Teaching.—As an academic study, politics arose as a division of practical philosophy, to which the theory of "natural law" was added in the seventeenth century. During the eighteenth century the Cameralistic sciences (see ECONOMICS) developed, and during the nineteenth century the separate political and socio-economic sciences were evolved. The systematic and juristic phase of political science has always been closely connected with the study of law; and considerable impetus, especially from the comparative standpoint, has been given by the recent growth of historical knowledge and interest.

German universities have held the foremost place in the development of political science, Dominicus Arumäus first lecturing on public law at the University of Jena between the years 1605-1637. Between 1661-1668 Pufendorf lectured on the new theory of "natural law" at the University of Heidelberg. During the latter part of the seventeenth and the first half of the eighteenth century the University of Halle, and during the latter half of the eighteenth century the University of Göttingen, were the chief centers of political studies. Beginning with the nineteenth century, political science shifted gradually from a "natural law" to an historical basis, and the political transformations through which Germany was passing gave additional impetus to political studies. Among the teachers of this period were Zachariä and Von Mohl at Heidelberg. By the middle of the nineteenth century the increasing knowledge of political institutions in other parts of the world made possible the comparative method of study. Bluntschli, who followed Von Mohl at Heidelberg and Gneist at Berlin, typified this development. Since the establishment of the German Empire a host of scholars, among whom may be mentioned Laband, Bric, and Jellinek, have emphasized the juridical rather than the historical method, and have paid particular attention to the nature of the federal State. In a few universities, Tübingen for example, studies relating to public affairs are combined in a separate faculty; but in most German universities the courses are grouped under the faculties of law or of philosophy. The first seminar in political science was organized at Jena in 1849. The *Statistische Seminar* at Berlin was founded in 1862, and between 1871-1876 a number of the leading universities established seminars for the investigation of political and economic problems.

The chief influence in the academic development of political science in France came from Laboulaye, a contemporary of Bluntschli in Germany and of Lieber in America. His lectures were given at the *Collège de France* during the third quarter of the last century. At the University of Paris, political science is taught in the faculty of law. Unusually valuable lectures in practical politics are given at the *École libre des sciences politiques*. In England the strong classical and mathematical traditions of Oxford and Cambridge offered considerable resistance to the newer social sciences. To the professorships of civil law established by Henry VIII, chairs of modern history were added at Cambridge in 1724 and at Oxford in 1854. By 1800 English law had been made a separate department in both universities. International law and diplomacy were introduced in 1854 at Oxford and in 1867 at Cambridge, and Oxford added in 1869 a professorship of jurisprudence. At present there is a professor of colonial history at Oxford and a

lecturer in politics at Cambridge. There are, however, no distinct departments of political science, as in the German or American universities, courses in government being incidental to law or to modern history. For example, Austin, Maine, Bryce, Dicey, and Pollock have held chairs of law, Sidgwick was a lecturer in moral science, and Freeman and Seely taught political science in connection with modern history. Seely's "conversation-class" at Cambridge was a sort of political science seminar. Separate chairs of political science are found in some of the younger universities, Manchester, for example. Much of the best writing on political subjects in England has been done by men not connected with the universities.

Jefferson's (*q.v.*) influence dominated the first teaching of politics in America. Changes made by him in 1779 at William and Mary College emphasized political and legal studies, and the curriculum which he constructed for the University of Virginia (1825) contained government as one of its main groups. Meanwhile, in the North, crude beginnings in political studies, usually in connection with philosophy, were being made by McVickar at Columbia (1817) and by Bowen at Harvard (1850). A more direct impetus was given by Woolsey, who, as president of Yale in 1847, taught political philosophy and international law. One of his students, Andrew D. White, who studied later in France and Germany, further emphasized political studies, first as professor at Michigan (1857-1862), then as president of Cornell (1868-1885). The most powerful stimulus to the teaching of political science was given by a German, Francis Lieber. In 1857, on the advice of McVickar, a separate professorship of history and political science was established at Columbia, and Lieber, who for twenty years had been teaching and writing at Columbia, S.C., was called to this chair. He introduced German methods and ideals, and began in America the fruitful coordination of political science with history, rather than, as formerly, with metaphysics. Lieber's professorship was abolished in 1865, but was reestablished in 1876 when John Burgess, who had studied in Germany and taught political science and history under Seelye at Amherst (1873-1876), took Lieber's place. In 1880 Burgess organized the School of Political Science at Columbia, Mayo Smith, Goodnow, and Munroe Smith being his first assistants. This school sent many students to study in Germany and has exerted a preponderant influence on the study and teaching of political science in this country. More recent teachers of politics include Hart and Lowell of Harvard, Dunning, Moore, and Beard of Columbia, Wilson of Princeton, Willoughby of Johns Hopkins, Merriam of Chicago, Rowe of Pennsylvania, Reinsch of Wisconsin, and Garner of Illinois.

Academic Organization and Method.—American colleges offer a considerable and growing amount of undergraduate instruction in political science. A recent study based on forty representative colleges shows that 72 per cent of these institutions offer courses in general political science or comparative government, 50 per cent teach American government, 45 per cent teach municipal government, and that courses in political theories, American politics, and American diplomacy are given in from 10 to 30 per cent of the number. In addition, fundamental courses in jurisprudence, international law, and American constitutional law are frequently offered. Some of these colleges have distinct departments of political science; but in others the work is organized under the department of history, or, in some cases, in connection with economics or sociology. The usual method of instruction is based upon general textbooks, and consists of lectures and discussions, collateral reading, oral and written reports, and periodical examinations. Clubs for the study of current events are often formed, and, when conditions permit, the operation of actual politics is observed or practical reform work is attempted. Since the courses are usually elective and limited to juniors and seniors, the total proportion of students receiving collegiate instruction in political science is comparatively small.

In the organization of the departments of political science in the leading American universities little uniformity can be found. At Chicago, Johns Hopkins, and Wisconsin there are separate departments of political science; at Harvard, history and government are grouped together; at Yale, the social sciences, law, and history are combined; and at Columbia, the faculty of political science includes the departments of history, economics, sociology, and political science proper. The usual courses include constitutional, administrative, and international law, political theory, comparative government, and certain phases of American government, especially municipal and colonial government, and political parties. The more elementary courses are usually limited to undergraduates; certain other courses are open to both undergraduates and graduates; and the more advanced courses are offered to graduates only. A clear-cut distinction between undergraduate and graduate courses and methods can scarcely be said to exist. However, in graduate courses the lectures are not dogmatic presentations of fundamental principles, but aim rather to open up the literature of the subject and to suggest its problems. In the seminar, instructors and students meet periodically for discussions and reports based on investigation and research. Voluntary clubs are often organized for the purpose of discussing or debating political topics, or listening to lectures on public affairs.

Two especially valuable series of publications, resulting from the investigations of university instructors and students, are the *Johns Hopkins University Studies in Historical and Political Science*, published monthly since 1883; and the *Columbia University Studies in History, Economics, and Public Law*, consisting of over one hundred monographs, issued since 1891. The study of political science is also furthered by associations affiliated with several of the large universities. The Academy of Political Science in the City of New York, organized in 1880 under the direction of the Faculty of Political Science of Columbia University, has, since 1886, published the *Political Science Quarterly*, and, since 1910, issued four volumes of Proceedings each year. The American Academy of Political and Social Science, organized in 1889, is affiliated with the University of Pennsylvania and publishes its *Annals* bimonthly. The American Political Science Association, established in 1903, is a national organization for "the encouragement of the scientific study of Politics, Public Law, Administration, and Diplomacy." It holds annual meetings, usually in conjunction with the American Historical Association, publishes the addresses delivered at such meetings, and controls the quarterly publication of the *American Political Science Review*.

Political Science and Practical Politics. — The study of political science lies in the border zone between those subjects that are especially of cultural value and those that are more specifically practical and professional. From the standpoint of the former, it brings the student in touch with the historical development of thought and of institutions, and familiarizes him with the issues and problems of modern civilization. From the standpoint of the latter it furnishes a direct foundation for law, government service, journalism, and good citizenship.

The increasing importance of political science in the university is both a cause and a result of the increasing importance of the university in practical politics. The proportion of college graduates in public office is growing each year; men actively engaged in university instruction have recently been candidates for important elective offices; and the influence of the university and its affiliated alumni associations is a valuable political asset. University trained men hold important positions in the civil service, and university teachers are frequently appointed to serve on governmental boards and commissions. The scorn in which the practical politician formerly held the academic teacher of politics is disappearing, and the State tends more and more to apply scientific political methods in actual government. History and present conditions are investigated before action is taken on new questions, and an increasing use is made of statistics. Political phenomena are observed and classified, and generalizations

are made from the data thus collected. For this work, dealing with conditions both at home and abroad, the State draws largely upon university teachers of political science. Especially close is the connection between academic and practical politics in the state universities of the Middle West; in some cases, as in Wisconsin, the university has become in effect a coordinate department of state administration, and exerts a powerful and direct influence upon public opinion and upon legislation.

In Europe an even closer connection between academic and practical politics is maintained by the Seminary of the Prussian Statistical Bureau at Berlin and the independent School of Political Sciences at Paris. The former, a government institution opened in 1862 under the chief of the Bureau of Statistics, aided by various university professors, is a laboratory of political science. It trains university students for the higher branches of the civil service and collects a vast amount of data valuable for both the scholar and the statesman. The latter, founded in 1871 as a private joint stock company, prepares for public affairs, especially for certain branches of the administration under the civil service system, and many of its lecturers are men prominent in public life. The establishment of a similar institution at Washington has often been urged.

Scope and Problems. — The scope of political science and its main divisions are determined by several broad categories under which the State may be viewed. There is, first, a distinction between the subjective and objective phases of the State. The former exists in the human mind and creates political theory; the latter exists in outward manifestations and gives rise to political institutions. Between political theory and political institutions the relation is close, each being both a cause and a result of the other. A second distinction views the State as both static and dynamic. From the former standpoint emphasis is laid on organization; from the latter, on function. Political science must tell what the state *is*, and what it *does*. The physical background of the State in population and territory, the constitutional organization of government, with its separation into legislative, executive, and judicial departments, and its division into national, local, and colonial agents, the governmental position of the electorate and of political parties, must all be described. The activities of the State are determined by the fundamental relations of individual to individual, some of which the State regulates under private law; the relations of State to individual, which the State determines in its public law; and the relations of State to State, which are regulated by the principles called international law. The share of individuals in governing authority and their freedom from governmental

interference open up important questions of sovereignty and liberty. Views as to the proper scope of state function vary from an extreme individualism to an extreme socialism. Opinions as to the proper nature of international relations show scarcely more agreement. A third distinction views the state as past, present, and future. The origin and political development of both theory and institutions must be traced; present conditions both as to organization and functions must be described; and future tendencies may either form the basis of political speculation or lead to active efforts at reform.

Certain fundamental changes have taken place during the past quarter century in the attitude of mind with which political scientists approach their subject. The doctrine of natural rights is now seldom referred to as a basis for political practice; neither are political events ascribed to the intervention of a divine Providence. There is also considerable hesitation in explaining broad and complex movements on the basis of racial characteristics. The speculative theorists and the builders of utopias have been replaced by men trained in historical research and in the scientific theory of evolution. Records of past political systems and theories are carefully studied, present day conditions are minutely analyzed and described, and principles of causation are diligently sought. Modern scholars, freeing themselves as far as possible of personal bias, and making little effort to praise or condemn, or to point morals, aim to view the origin, development, organization, relations, and functions of the state, in the light of past conditions and present tendencies, constantly remembering the close connection between the political activities of mankind and those other phases of development which make up the total process of social evolution. R. G. G.

See CIVICS for treatment of the subject in the lower schools.

POLYGON — A word derived from the Greek and meaning many-angled. In elementary geometry the term is usually limited to convex plane figures bounded by a continuous line, made up of straight lines. We may, however, have concave polygons, cross polygons, and polygons that are not in the same plane (skew polygons).

A polygon is said to be regular if its sides are equal and its angles are equal. The study

of the regular polygons forms a part of the work in elementary plane geometry. Of the principles of polygons, one of the most important is that relating to the sum of the angles, this sum being equal to $(n-2)$ times 2 right angles. The study of the stellar polygon was prominent in medieval education. D. E. S.

POLYGONAL NUMBERS — The Greeks paid much attention to the theory of numbers, and there still remain in arithmetic certain relics of their activity in this field, as in the treatment of prime numbers, even and odd numbers, and square and cube numbers. A square number derives its name from the fact that 4, 9, 16, 25 . . . dots can be arranged in the form of a geometric square. A square number is a special form of a polygonal number, for it is possible to arrange the dots in the form of other polygons, such as triangles, pentagons, etc. Among the polygonal numbers studied by the Greeks, and found in the medieval education, are the following:—

Triangular,	1,	3,	6,	10,	15,	...
Square,	1,	4,	9,	25,	36,	...
Pentagonal,	1,	5,	12,	22,	35,	...
Hexagonal,	1,	6,	15,	28,	45,	...

With the exception of square numbers the polygonal numbers are no longer studied.

D. E. S.

POLYHEDRON. — A term derived from the Greek and meaning many-faced, or many-seated. A regular polyhedron has all of its faces congruent regular polygons. There are five regular convex polyhedrons, and these were studied so extensively in the school of Plato as to have the name of "Platonic bodies." The Greeks attributed particular mystic significance to these various bodies. One of the fundamental properties of convex

POLYHEDRON

polyhedrons is that the number of faces plus the number of vertices equals the number of edges plus two. The polyhedrons of chief importance in the teaching of elementary mathematics are usually considered to be those which are needed in the problems in mensuration; namely, the cube, parallelepiped, prism, pyramid, and frustum of a pyramid. As a formula of mensuration the most important one is the so-called prismatoid formula, that $v = \frac{h}{6}(b + b' + 4m)$ where h = height, b and

b' = the bases, and m = a mid-section parallel to the base. (See GEOMETRY.) D. E. S.
